**UNITED STATES
UNITED STATES VOR RECEIVER CHECK SIGNALS**

INTRODUCTION

Federal Aviation Regulations (FAR 91.171) provides for certain VOR equipment accuracy checks prior to flight under instrument flight rules (IFR). To comply with this requirement and to ensure satisfactory operation of the airborne system, the FAA has provided pilots with the following means of checking VOR receiver accuracy:

- a. VOT or a radiated test signal from an appropriately rated radio repair station.
- b. Certified airborne check points.
- c. Certified check points on the airport surface.

The FAA VOR test facility (VOT) transmits a test signal which provides users a convenient means to determine the operational status and accuracy of a VOR receiver while on the ground where a VOT is located. The airborne use of VOT is permitted; however, its use is strictly limited to specifically authorized areas/altitudes.

To use the VOT service, tune in the VOT frequency on your VOR receiver. With the Course Deviation Indicator (CDI) centered, the omni-bearing selector should read 0 degrees with the to/from indication showing "from" or the omni-bearing selector should read 180 degrees with the to/from indication showing "to." Should the VOR receiver operate an RMI (Radio Magnetic Indicator), it will indicate 180 degrees on any omni-bearing selector (OBS) setting. Two means of identification are used. One is a series of dots and the other is a continuous tone. Information concerning an individual test signal can be obtained from the local FSS.

Airborne and ground check points consist of certified radials that should be received at specific points on the airport surface or over specific landmarks while airborne in the immediate vicinity of the airport.

- a. Should an error in excess of +/- 4 degrees be indicated through use of a ground check, or +/- 6 degrees using the airborne check, IFR flight shall not be attempted without first correcting the source of the error.

CAUTION: No correction other than the correction card figures supplied by the manufacturer should be applied in making these VOR receiver checks.

- b. If a dual system VOR (units independent of each other except for the antenna) is installed in the aircraft one system may be checked against the other. Turn both systems to the same VOR ground facility and note the indicated bearing to that station. The maximum permissible variations between the two indicated bearings is 4 degrees.

EXPLANATION OF LISTINGS

VORs are listed by their facility name. When followed by an airport name (in parentheses) there is a Ground (G) check point on the airport or an Airborne (A) check point on or near that airport.

VOTs are listed by the city name of the airport they serve, followed by the airport name in parentheses.

The following information is provided:

- Type of check, Ground (G) or Airborne (A).

**UNITED STATES
UNITED STATES VOR RECEIVER CHECK SIGNALS**

- For VOR check points - VOR frequency and identifier. Bearing in degrees magnetic outbound from the VOR; location of the check point (distances are in nautical miles); altitude (in feet MSL).
- For VOTs – Frequency. When VOT can be used for an Airborne (A) check, the appropriate distances and altitudes are included. Additionally, areas where a VOT cannot be received are identified.

ALASKA
ALASKA VOR RECEIVER CHECK SIGNALS

INTRODUCTION

Airborne and ground check points consist of certified radials that should be received at specific points on the airport surface, or over specific landmarks while airborne in the immediate vicinity of the airport.

Should an error in excess of +/- 4 degrees be indicated through use of a ground check, or +/- 6 degrees using the airborne check, IFR flight shall not be attempted without first correcting the source of the error.

CAUTION: No correction other than the "correction card" figures supplied by the manufacturer should be applied in making these VOR receiver checks.

AIRBORNE RECEIVER CHECK POINTS

BELLINGHAM	108.5 BLI	159°; 5.5 NM, over Nooksack River/15 bridge 1700' MSL.
BETHEL	114.1 BET	076°; 11.2 NM, over Rwy 36 at Kwethluk strip; 1500' MSL.
COLD BAY	112.6 CDB	127°; 7.0 NM, over NW end of abandoned airstrip SE of Cold Bay Apt; 1000' MSL.
FAIRBANKS (Intl)	108.6 FAI	204°; 8.5 NM, center of grass airfield in bend of Tanana river; 2000' MSL.
GULKANA	115.6 GKN	327°; 10.2 NM, small bldg on NE side of pipeline; 3500' MSL.
HOMER	114.6 HOM	153°; 6.6 NM, over center of white oil tank; 1000' MSL.
KENAI (Mun)	117.6 ENA	091°; 14.0 NM, over Moose River Bridge; 1500' MSL.
KING SALMON	112.8 AKN	257°; 8.0 NM, over Standard Oil storage tank in Naknek Village on the bank of Naknek River; 1100' MSL.
McGRATH	115.5 MCG	263°; 11.7 NM over Takotna Equip Garage; 3000' MSL.
NOME	115.0 OME	276°; 5.3 NM, center of intersecting rwys; 1100' MSL.
SISTERS ISLAND (Gustavus)	114.0 SSR	297°; 20.4 NM, over intersection of rwys at Gustavus Apt; 1500' MSL.

ALASKA

ALASKA VOR RECEIVER CHECK SIGNALS

GROUND RECEIVER CHECK POINTS

EARECKSON AS	109.0 SYA	096°; 1.8 NM, twy in front of twr.
LADD AAF	108.6 FAI	058°; 10.8 NM, south ramp adjacent to Rwy 25L touchdown.

ALASKA

USAF RADAR ASSISTANCE SERVICE

Radar Assistance Service is designed to assist aircraft in flight to avoid areas of potentially hazardous conditions such as weather, anti-aircraft artillery zones, restricted areas, warning areas, etc. This service does not provide for routine navigational assistance, the relay of normal position reports, or general air traffic information.

PROCEDURES

- a. A pilot will request Radar Assistance Service through use of the term "Radar Assistance" using the following radio frequency:

Civil Aircraft — 126.2 Northern DEW stations and Alaska ACW radar stations.

EXAMPLE: "Radar Assistance" THIS IS (Identification, Position, Heading), IFR/VFR FLIGHT PLAN, OVER. Thereafter the pilot will use the call sign of the radar unit which responds.

- b. Whenever airborne equipment permits, the pilot on an IFR flight plan will continue to guard the normal enroute ATC frequency while in contact with the radar unit. When this is possible, it will not be necessary for the pilot to advise the ATC guard stations that he is about to contact the radar unit for advisory service.
- c. If it is necessary to leave the normal enroute ATC frequency in order to contact the radar unit, the pilot on an IFR flight plan will request permission (direct or via appropriate communications station) from the Air Route Traffic Control Center (ARTCC) to leave the ATC frequency.
- d. The pilot should immediately return to the normal enroute frequency and report when:
 1. The procedural word "Unable" (used by radar units when assistance service cannot be furnished for any reason) is received from the radar station. The receipt of this word will be final and no further explanation will be required.
 2. Radio contact with the radar unit is lost.
 3. Notified by the radar unit that radar contact has been lost.
 4. The assistance service is completed.
- e. Radar assistance information to a pilot is advisory only and does not relieve the pilot of his responsibility to see and avoid other aircraft. Radar detected traffic and weather advisories are provided only as an aid and no control or responsibility will be assumed by the USAF or its operating agents. Pilots are reminded that the surveillance radar utilized does not provide altitude information and may not display all aircraft.

Meteorology

Meteorology Data - North America

**CANADA
GENERAL INFORMATION****SECTION 1****1.1 GENERAL**

The Minister of Transport is responsible for the development and regulation of aeronautics and the supervision of all matters connected with aeronautics.

The responsibility for the provision of aviation weather services in Canadian airspace and any other airspace in respect of which Canada has the responsibility for the provision of ATC services, has been designated to NAV CANADA by the Minister of Transport.

NAV CANADA is responsible for a range of aviation weather services, some of which are provided to it under a contractual agreement with Environment and Climate Change Canada (ECCC). These services include most civilian aviation weather forecasts. NAV CANADA is responsible for determining the location and frequency of aviation weather observations and forecasts, and for the dissemination of this information for aviation purposes.

In addition to the aviation weather services provided by NAV CANADA, other aviation service providers may offer weather services in support of operations at local airports that have light traffic, are private, and/or are used primarily in support of private industry, such as mining or other similar operations.

The Department of National Defence arranges for the provision of aviation weather services at military airports.

1.1.1 Meteorological Information

In accordance with *Canadian Aviation Regulation* (CAR) 804.01(1), the majority of standards for aviation weather services are found in: *International Civil Aviation Organization* (ICAO) Annex 3, the *Manual of Standards and Procedures for Aviation Weather Forecasts* (MANAIR), and the *Manual of Surface Weather Observations Standards* (MANOBS). The two manuals can be obtained from ECCC's Web site at <https://www.canada.ca/en/environment-climate-change/services/weather-manuals-documentation.html>, while Annex 3 can be obtained from ICAO (see also — METEOROLOGY — METEOROLOGICAL SERVICE FOR INTERNATIONAL AIR NAVIGATION — ANNEX 3). Revisions to MANOBS and MANAIR will become effective on 2 December 2021.

Enquiries relating to the provision of aviation weather services should be addressed to:

NAV CANADA**Aviation Weather Services**

Address: 151 Slater Street

Toll-free (North America) 1-877-663-6656

CANADA GENERAL INFORMATION

E-Mail: service@navcanada.ca

Enquiries relating to regulations and standards for aviation weather services should be addressed to:

Flight Standards (AARTA)

Transport Canada

Address: Ottawa

ON

K1A 0N8

Tel: 1-800-305-2059

Fax: 613-957-4208

E-Mail: TC.Flights.Standards-Normesdevol.TC@tc.gc.ca

Enquiries related to operational issues, notification requirements, and the regulatory compliance of aviation weather services can be referred to the TC regional office or by e-mail to: TC.ANSWeatherInfo-InfoMeteoSNA.TC@tc.gc.ca.

1.1.2 Meteorological Services Available

Aviation weather information is available from NAV CANADA FICs. Telephone numbers and hours of services are listed in the CFS and the CWAS (not published herein).

1.1.3 Aviation Weather Services

a. *Pilot Briefing Service*

The Pilot Briefing Service is provided by NAV CANADA FICs to accommodate pilots at the pre-flight planning stage and for information updates while enroute. Flight service specialists can access and display a full range of weather charts, imagery (i.e., satellite, lightning and radar) and aeronautical information (such as NOTAM, RSC and CRFI). They are qualified to provide briefings, consultation and advice, and to interpret meteorological information. (See ATC — FLIGHT PLANNING, Pilot Briefing Service, paragraph 3.2 for details.)

b. *Aviation Weather Web Site (AWWS)*

NAV CANADA's aviation weather web site (AWWS), available at <https://flightplanning.navcanada.ca/>, and collaborative flight planning system, available at <https://plan.navcanada.ca>, offer aviation weather products, NOTAM and the ability to file flight plans. For more information, visit www.navcanada.ca.

Pilots operating near the border should note that U.S. METAR, SPECI and TAF must be obtained through the Aviation Digital Data Service (ADDS), available at www.aviation-weather.gov/adds/.

c. *Other Pilot Weather Services*

In accordance with an arrangement with the U.S. National Weather Service, digital upper level wind and temperature forecasts are available to operators in Canada for planning inter-

CANADA GENERAL INFORMATION

national flights. Digital forecasts are also available to the Gander OAC for planning transatlantic flights.

Aviation weather flight documentation is provided, subject to prior notification, as determined by the local weather service outlet in consultation with the operator's local representative.

Operators are responsible for notifying NAV CANADA's Aviation Weather Services of new requirements. (See 1.1.1 for the address.) Where indicated, altimeter settings in weather reports from U.S. airports may be used as a RASS.

1.1.4 Weather Service Information

When planning a flight, pilots can obtain aviation weather and aeronautical information and file a flight plan through a NAV CANADA FIC. (See ATC — FLIGHT PLANNING, Pilot Briefing Service, for details.)

Radio communication should be established with an FIC on an FISE frequency if in-flight information is required to assist in making a decision or to terminate a flight, or to alter course before adverse weather conditions are encountered.

Pilot requests for initial weather briefings while airborne are not encouraged because this practice leads to frequency congestion.

1.1.5 Weather Information from Air Traffic Service (ATS)

All airports with operational ATS will provide, on initial contact or as soon as practicable, the current wind and altimeter information unless it is known that the aircraft already has this information. ATS procedures require that wind information be transmitted with landing and take-off clearance only when the wind speed is 15 kts or greater. Wind velocity (direction and speed) data is typically updated every five seconds using a running 2-minute average. Variations to the wind speed (gusts) and/or wind direction are based on wind data from the previous 10 minutes.

At airports with an operational ATIS, the full details of the most recent METAR or SPECI will be included in the recorded message. In rare circumstances, such as during rapidly changing weather conditions, this information will be provided directly by ATS. Where ATIS is not operational, updated current information about weather elements from METAR/SPECI is available on request.

RVR observations are obtained by forward-scatter sensors. Observations representative of the touchdown and, where available, midpoint and roll out visibility, averaged over 1 minute and based on the light setting in use, are automatically displayed in digital form in the local ATS unit. When RVR is less than 6000 ft, the current RVR value for the runway will be given to departing and arriving aircraft and when landing information is given to the aircraft on final approach. However, at any time the pilot can request an RVR value during any phase of the approach or landing.

RVR is included in METARs and SPECIs when it is 6000 ft or less for the runway in use and/or the visibility is 1 SM or less. The RVR is presented in ICAO format and is based on a 10-minute average of the maximum runway light setting. Refer to the METAR example (METEOROLOGY — Section 3.8.3) for further details.

**CANADA
GENERAL INFORMATION****1.1.6 Pilot Reports****1.1.6.1 Pilot Weather Reports PIREPs**

Pilots are urged to volunteer reports of cloud tops, upper cloud layers, cruising level wind velocity, and other meteorological information which may be significant to safe or comfortable flight conditions. The information is also used by ECCC meteorologists to confirm or amend aviation weather forecasts. PIREPs less than one hour old that contain information about conditions considered to be a hazard to aviation are broadcast immediately to aircraft in the affected area and will be included in subsequent scheduled weather broadcasts. PIREPs are also transmitted under the headings “UACN10” for normal PIREPs and “UACN01” or “UUA” for urgent PIREPs. More information on PIREPs is contained in METEOROLOGY — PILOT REPORTS — Section 2.

1.1.7 Applicable International Civil Aviation Organization (ICAO) and World Meteorological Organization (WMO) Documents

Whereas ICAO determines the standards and recommended practices with respect to meteorological service for international air navigation, the World Meteorological Organization (WMO) determines and reports the internationally agreed upon code formats for the reports and forecasts. ICAO and WMO documents applicable to aviation meteorology are as follows:

ICAO Annex 3 — Meteorological Service for International Air Navigation,

WMO Doc 306 — Manual on Codes.

Most WMO documents can be downloaded, without cost, from the Internet. WMO documents may be ordered directly from the WMO Secretariat in Geneva, Switzerland. ICAO documents may be purchased from the ICAO Headquarters in Montréal. The two relevant addresses are listed below:

World Meteorological Organization (WMO)

Sales and Distribution of Publications

Address: 7bis, Avenue De La Paix

P.O. Box 2300

CH-1211 Geneva 2

Switzerland

Tel: +41-22-730-8111

Fax: +41-22-730-8181

Internet: www.wmo.int

International Civil Aviation Organization (ICAO)

Distribution Sales Unit

Address: Suite 305

999 Robert-Bourassa Boulevard

Montreal

QC

H3C 5H7

CANADA GENERAL INFORMATION

Tel: 514-954-8022

Internet: www.icao.int

Pilots flying outside of North America should consult the differences filed by other member states as outlined in WMO Doc. 306, or in the Aeronautical Information Publication of each country.

1.1.8 Differences from International Civil Aviation Organization (ICAO) Annex 3

CAR 804.01(1)(a) incorporates by reference standards contained in ICAO Annex 3. The current version of Annex 3 includes Amendment 80, which became applicable on November 4, 2021. In accordance with CAR 800.01(2), the incorporation by reference of Annex 3 as a standard “includes the differences notified to ICAO by the Government of Canada in respect of the standards specified in that annex.” The full details of these state differences are included in the *AIP Canada (ICAO)*, as published and disseminated by NAV CANADA.

1.1.9 Pilot Responsibility

Pilots must be aware of the requirements of CAR 602.72: “The pilot-in-command of an aircraft shall, before commencing a flight, be familiar with the available weather information that is appropriate to the intended flight.”

1.2 METEOROLOGICAL OBSERVATION AND REPORTS

1.2.1 Type and Frequency of Observations

METARs are coded weather observations that are taken each hour at over 200 airports and other locations in Canada. In addition, SPECIs are issued whenever weather conditions cross specified criteria. See METEOROLOGY — APPENDICES — AERODROME ROUTINE METEOROLOGICAL REPORTS (METARs) — Section 3.8.3. For details on SPECI criteria, see Section 3.8.4.

The location of sensors used to determine Runway Visual Range is specified on the Jeppesen Airport Charts.

1.2.2 Flight Weather Documentation

Pilots must use the most recent weather information available when flight planning and be aware of scheduled weather information updates. Pilots must also remain vigilant for pertinent unscheduled weather updates or amendments.

Flight weather documentation should include, as appropriate: the relevant GFAs, AIRMETs, SIGMETs, TAFs, METARs, SPECIs, PIREPs, and upper wind and temperature forecasts.

There are two distinct methods of reporting cloud bases. It is vital for the pilot to be able to distinguish and recognize which method of reporting is in use. Heights in METARs and TAFs are always stated as height above ground level. On the other hand, heights in GFAs and PIREPs are normally stated as height above sea level, since terrain heights are variable over the larger area covered. If heights are not ASL in GFAs, this is always highlighted by statements such as “CIGS 2-4 AGL.”

1.2.3 Weather Services Definitions in Flight Publications

The terminology used to describe aviation weather services is as follows:

CANADA GENERAL INFORMATION

- a. *METAR* — METAR and SPECI weather observation program taken by a qualified human observer.
- b. *METAR AUTO* — METAR AUTO and SPECI AUTO are weather observations taken by a stand-alone AWOS with noted enhancements (see METEOROLOGY — APPENDICES — AERODROME ROUTINE METEOROLOGICAL REPORTS (METARs) Section 3.8.5). METAR AUTO systems located outside of the Canadian Lightning Detection Network coverage area do not receive lightning data and therefore are unable to report thunderstorm or lightning activity.

Examples of METAR AUTO stations are the NAV CANADA AWOS (NC AWOS) and DND AWOS.

- c. *LWIS* — An automated weather system which produces an hourly LWIS report containing wind speed and direction; temperature; dew point; and altimeter setting only.
- d. *AUTO* — An automated weather system that does not meet requirements to produce a METAR AUTO, SPECI AUTO or LWIS report. These systems can report a variety of observed weather elements. Contact the airport operator (OPR) for further information on the specifics of the system. Some of these systems may have associated VHF transmissions of their reports.
- e. *WxCam* — Indicates that a NAV CANADA aviation weather camera is installed at the site. Still images are transmitted to the NAV CANADA AWWWS at 10-minute intervals.
- f. *Webcam* — Indicates that one or more cameras not belonging to NAV CANADA have been installed at this location. Contact the airport operator for further information on the specifics of the camera system.
- g. *ALTIMETER* — Altimeter setting report observed from two aircraft altimeters. The private altimeter setting report is a weather service provided in support of an AU. Contact the airport operator for further information on the service.
- h. *WIND* — Human assessment of wind speed and direction. The private wind speed and direction report is a weather service provided in support of an AU. Contact the airport operator for further information on the service.
- i. *LAWO* — A visual observation of prevailing tower visibility and tower ceiling made by airport controllers from inside the tower cab in order to provide limited weather information to support local flight operations. These observations are not intended for transmission, distribution, or use outside the control zone. This information is normally included in the local ATIS recording and updated as required or passed verbally to aircraft arriving at, and departing from, the local airport.

Observed weather information, observations, and forecasts originating from any non-NAV CANADA weather service, other than DND, are considered a private meteorological service.

Stand-alone METAR AUTO and LWIS reports are available during published hours through normal meteorological information systems. At some sites an automated voice broadcast of the latest observation is available via VHF transmitter. In these cases, the VHF frequency is displayed

CANADA

GENERAL INFORMATION

in the COMM entry of the CFS Aerodrome/Facility Directory (e.g., COMM AWOS 124.7, COMM AUTO 122.025) (not published herein).

The hours of coverage for METAR, METAR AUTO and LWIS are given (e.g. METAR 09-21Z). At sites where coverage is 24 hr, the coverage is listed as H24 (e.g. METAR H24, METAR AUTO H24).

Sites that provide unspecified limited hours of coverage will be listed as ltd hrs (e.g. ALTIMETER ltd hrs). Contact the airport operator for further information on the hours of operation.

Weather services that are not included in the flight publications exist. These are of an unknown performance and can be used for VFR flights at the discretion of the pilot. However, unpublished weather services cannot be used in support of instrument flight procedures.

1.2.4 Automated Weather Observation Stations (AWOS)

1.2.4.1 Overview

AWOS, LWIS and AUTO refer to automated equipment used as a means to provide an aviation weather service with AWOS typically referring to equipment with more sensors. The services that can be provided by these systems are either full METAR AUTO/SPECI AUTO or some subset thereof. LWIS provides a basic group of four elements and issues an hourly report. Operators of automated weather stations that are used to support instrument flight procedures are required to document the characteristics of their systems and to provide aircraft operators with suitable descriptions, upon request.

AWOS and LWIS operated by NAV CANADA have common performance characteristics across the country. A description of the performance characteristics of these systems can be found in METEOROLOGY — APPENDICES — AERODROME ROUTINE METEOROLOGICAL REPORTS and Limited Weather Information System (LWIS) Reports — Section 3.8.5.

The subset of weather elements provided by AUTO may vary from only one element to almost a full METAR AUTO/SPECI AUTO. Any automated system that is not capable of reporting all the elements required to generate METAR AUTO/SPECI AUTO reports and support any associated TAF should be referred to as AUTO or LWIS. Some local service providers may refer to their systems as AWOS, but if they do not support METAR AUTO/SPECI AUTO, then they will be listed as AUTO in the CFS (not published herein).

NOTE: The United States uses the term “automated surface observation system” (ASOS) as the equivalent to Canadian AWOS that provide METAR AUTO reports. Typically, usage of the term AWOS in the United States is equivalent to the Canadian LWIS but with several defined levels of observation capabilities. Further details regarding performance characteristics and reporting practices can be found in the FAA’s Aeronautical Information Manual. (See also JEPPESEN — METEOROLOGY — UNITED STATES — SAFETY OF FLIGHT or METEOROLOGY — UNITED STATES — METEOROLOGY.)

1.2.4.2 Visual Flight Rules (VFR) Weather Stations

Some weather stations are intended exclusively for local use by VFR operators. These stations do not meet the requirements of a useable altimeter setting or of wind reports for IFR procedures.

CANADA
GENERAL INFORMATION

These stations are not permitted at airports that have IAPs and they are not published in the CFS (not published herein). Pilots making use of these stations do so at their discretion for VFR. If the reports from such stations are being broadcast as an advisory, the frequency will be mentioned in the COMM section of the CFS Aerodrome/Facility Directory (not published herein) along with an annotation stating that the reports cannot be used for IFR. Some private automated stations may disseminate weather information via the Internet and this information should be for VFR flight advisory use only. Pilots should contact the airport operator if they require additional information.

1.2.5 Automatic Aerodrome Routine Meteorological Reports (METAR AUTO) and Limited Weather Information System (LWIS) Reports

1.2.5.1 Automatic Aerodrome Routine Meteorological Reports (METAR AUTO)

METAR AUTO reports are based on NAV CANADA or DND AWOS systems, which are comprised of a set of meteorological sensors, a data processing system, a communications system, and an optional VGSS and VHF transmitter. In addition, weather cameras are installed at NAV CANADA locations. METAR AUTO reports may be used to support a TAF at the associated airport.

METAR AUTO reports depend on either a NAV CANADA- or DND-developed system or on a commercial system that complies with TC requirements for aviation use. The applicable standards are contained in MANOBS.

Observations are distributed in the form of METAR AUTO and must be properly coded and supplemented by SPECI AUTO when SPECI thresholds are crossed. At a minimum, the following are observed and reported:

- wind (direction, speed and gusts);
- altimeter setting (these include multiple sensors as a fail-safe);
- air temperature;
- dew point;
- visibility;
- cloud height;
- sky coverage (of detected cloud);
- precipitation occurrence and type;
- fog, freezing fog, haze, blowing snow and mist;
- thunderstorm detection capability; and
- icing.

In addition, some reports include RVR where this information is available.

For more information on METAR AUTO reports, refer to METEOROLOGY — APPENDICES — AERODROME ROUTINE METEOROLOGICAL REPORTS (METARs) — METAR AUTO and Limited Weather Information System (LWIS) Reports.

**CANADA
GENERAL INFORMATION****1.2.5.2 Limited Weather Information System (LWIS) Reports**

An LWIS comprises automated meteorological sensors, a data processing system, a communication system, and an optional voice generator sub-system (VGSS) with VHF transmitter. The LWIS collects limited meteorological data, produces LWIS reports and transmits data to ATS facilities on the hour. The LWIS also transmits data updated every minute to the affiliated VGSS and VHF transmitter units.

These systems were developed to meet a defined level of service requirement for NAV CANADA.

Any LWIS used for civil aviation purposes must comply with TC requirements and be equipped with sensors to report, at a minimum, the following:

- wind (direction, speed and gusts);
- altimeter setting (these include multiple sensors as a fail-safe);
- air temperature; and
- dew point.

Wind direction is reported in degrees true except for the VGSS, which reports wind direction in degrees magnetic in SDA.

Except for the DND stations in the High Arctic that do not provide dew point information, any automated system that reports fewer elements than the standard four required for an LWIS should be referred to as an AUTO. For more information on LWIS, please refer to METEOROLOGY — APPENDICES — AERODROME ROUTINE METEOROLOGICAL REPORTS (METARs) — METAR AUTO and Limited Weather Information System (LWIS) Reports.

1.2.6 Automatic (AUTO) Reports

The term AUTO is used to describe all other automated aviation weather reports that have demonstrated compliance with TC requirements and are useable for IFR flight. However, they have a wide variety of performance characteristics and may be referred to locally by different labels, most often as AWOS. Contact the airport operator for more information on the characteristics of local systems.

1.2.7 Weather Services in Support of Approach UNICOM (AU)

Weather information is not useable for instrument procedures unless it complies with the requirements of CAR 804, including MANOBS incorporated by reference, or a related national exemption.

An approach UNICOM (AU) is an air-ground communications service that can provide approach and landing information to IFR pilots. The service provider is required to ensure that requirements detailed in Appendix 4 of MANOBS (not published herein) are met for:

- a. meteorological instruments and observational methods used; and
- b. personnel qualifications and training.

AU service may include the use of two aircraft altimeters to observe and report the altimeter setting and the human estimation of wind speed and direction for the selection of the most into-wind

CANADA GENERAL INFORMATION

runway. The estimated wind direction and speed are considered current for a period not exceeding 10 min.

At a few AU locations, fully automated systems are used to measure atmospheric pressure. This data is used to determine the altimeter setting that is relayed to pilots. In these cases, the reported altimeter setting must comply with the same requirements applied to the altimeter component of METAR AUTO/SPECI AUTO.

Further details related to AU services are contained in Appendix 4 of MANOBS.

Any weather information provided by a UNICOM, as opposed to an AU, is not useable for instrument procedures; alternative uses are entirely at the pilot's discretion.

1.2.8 Runway Visibility Assessment (RVA)

At airports where RVR is not provided, qualified persons may, in accordance with the requirements of the runway visibility assessment standards referenced by CAR 804, provide an assessment of runway visibility. Instrument-rated pilots may also provide such assessments in accordance with CAR 602.131.

An RVA is valid for only 20 minutes after it has been established.

1.3 METEOROLOGICAL FORECASTS AND CHARTS

1.3.1 Flight Information Centre (FIC) Hours of Service and Telephone Numbers

All FICs provide 24-hour service. FIC telephone numbers are provided in the CFS. Pilots dialing the common toll-free number 1-866-WXBRIEF (992-7433) or 1-866-GOMÉTÉO will automatically be routed to the FIC serving the area from which the call is being made.

1.3.2 World Area Forecast System (WAFS) Charts

WAFS aviation weather charts are disseminated as required. These include prognostic significant weather charts for the North Pacific, the Caribbean and northern South America, the North Atlantic, Canada and the United States.

1.3.3 Aerodrome Forecasts TAFs

TAFs are prepared for approximately 180 airports across Canada. TAFs are limited to airports for which METAR and SPECI reports are available. The forecasts are generally prepared four times daily with periods of validity up to a maximum of 30 hours. See Meteorology 3.7 for more information on TAFs, including when they are issued, their periods of validity, and decoding instructions.

TAFs are issued in TAF code, with amendments as required.

1.3.4 Airport Advisory Forecasts

Airport advisories are forecasts that are issued in TAF format except that 'ADVISORY' is added immediately after the period of validity group. They are issued in the place of a TAF in the following circumstances:

- a. Offsite: the forecast is based on observations that have been taken offsite, more than 1.6 NM from the airport center, and are not considered to be representative of weather conditions at the airport;

CANADA GENERAL INFORMATION

- b. Observation Incomplete: the forecast is based on observations which have regularly missing or incomplete data; or
- c. No Specials: the forecast is based on observations from a station with a limited observing program that does not issue SPECI reports.

In each case, after the period of coverage group, the advisory forecast will be labelled with the word "ADVISORY" and the appropriate qualifier (OFFSITE, OBS INCOMPLETE or NO SPECI).

1.3.5 Coastal Weather

Float plane operators can also obtain coastal marine weather on HF and VHF-FM frequencies from some Canadian Coast Guard stations. Frequencies and time of broadcast are contained in two Canadian Coast Guard publications: *Radio Aids to Marine Navigation (Pacific, and Arctic)* and *Radio Aids to Marine Navigation (Atlantic, St. Lawrence, Great Lakes, Lake Winnipeg and Arctic)*. These two publications are published annually and are available on the Canadian Coast Guard Web site.

1.3.6 Graphic Area Forecasts (GFAs) and AIRMET

GFAs are issued as a series of temporally adjusted weather charts for Canadian Domestic Airspace and distributed on a routine or on-request basis. These forecasts are prepared four times daily for 7 regions across the country with a validity period of 12 hr and an IFR outlook for a further 12 hr. See METEOROLOGY — APPENDICES — Graphic Area Forecast (GFA) for issue, periods of validity and decoding instructions. Once issued, a SIGMET or AIRMET message automatically amends the current and relevant GFA. A full description of this product can be found in METEOROLOGY — APPENDICES — AIRMET.

1.3.7 Upper Level Wind and Temperature Forecasts (FD)

Alphanumeric upper level wind and temperature forecasts (FD) are routinely prepared for 142 sites in Canada. FD forecasts are produced by a super-computer model of the atmosphere called a Numerical Weather Prediction (NWP) model, which is run twice per day (00Z and 12Z) after collecting and analyzing weather observation data from around the world.

An FD forecast based on the 12Z NWP model run on the fifth day of the month would include the following text at the top of the forecast data, "FCST BASED on 051200 DATA". The text "DATA VALID 060000" in the FD forecast indicates that the temperature and wind velocity data is forecast to be most representative of conditions at 00Z on the sixth day of the month. FD forecast data can be used for several hours before or after the stated valid time. This is indicated by the text "FOR USE 21 – 06", which means that this particular forecast may be used for a 9-hour period from 21Z to 06Z.

During flight planning, care must be exercised to ensure that the correct FD forecast is selected and the associated "FOR USE" coverage is appropriate for the time of the proposed flight.

Forecasts in digital form of the winds and temperatures aloft (FB), an improvement over FD forecasts, are now available over the phone. FB forecasts are updated four times per day. Over the next couple of years, FB forecasts will gradually replace FD forecasts for most flight planning pur-

CANADA

GENERAL INFORMATION

poses. Further information is available in the MANAIR, which can be found on Environment Canada's Web site.

1.3.8 ATC Weather Assistance

ATC will issue information on significant weather and assist pilots in avoiding weather areas when requested. However, for reasons of safety, an IFR flight must not deviate from an assigned course or altitude/flight level without a proper ATC clearance. When weather conditions encountered are so severe that an immediate deviation is determined to be necessary, and time will not permit approval by ATC, the pilot's emergency authority may be exercised. However, when such action is taken, ATC should be advised as soon as practicable.

When a pilot requests clearance for a route deviation or for an ATC radar vector, the controller must evaluate the air traffic situation in the affected area and coordinate with other controllers before replying to the request.

It should be remembered that the controller's primary function is to provide safe separation between aircraft. Any additional service, such as weather avoidance assistance, can only be provided to the extent that it does not detract from the primary function. Also note that the separation workload for the controller generally increases when weather disrupts the usual flow of traffic. ATC radar limitations and frequency congestion is also a factor in limiting the controller's capability to provide additional services.

It is important, therefore, that the request for a deviation or radar vector be forwarded to ATC as far in advance as possible. Delay in submitting it may delay or even preclude ATC approval or require that additional restrictions be placed on the clearance. Pilots should respond to a weather advisory by requesting: a deviation off course and stating the estimated number of miles and the direction of the requested deviation; a new route to avoid the affected area; a change of altitude; or, radar vectors around the affected areas.

The following information should be given to ATC as early as possible when requesting clearance to detour around weather activity:

- a. proposed route and extent of detour (direction and distance);
- b. flight conditions IMC or VMC; and
- c. whether or not the aircraft is equipped with a functioning cockpit weather radar.

The assistance that might be given by ATC will depend upon the weather information available to controllers. Owing to the often transitory nature of severe weather situations, the controller's weather information may be of only limited value if based on weather observed on radar only. Frequent updates by pilots, giving specific information as to the area affected, altitudes, intensity and nature of the severe weather, are of considerable value. Such PIREPs receive immediate and widespread dissemination to aircrew, dispatchers and aviation forecasters.

1.3.9 Supplementary Information

1.3.9.1 Weather Radar

Weather radars typically present a display of precipitation within 150 NM of the facility site; storms of considerable height and intensity can be seen at greater ranges. However, it should be noted

CANADA GENERAL INFORMATION

that these radars cannot detect turbulence. The turbulence associated with a very heavy rate of rainfall will generally be significantly more severe than that associated with light rainfall.

Environment Canada (EC) and the Department of National Defense (DND) operate a series of weather radars across Canada that provide frequent reports of precipitation echo tops and precipitation reflectivity. Radar images are updated approximately every 10 minutes for individual radars. A color composite radar product, which depicts either echo tops or precipitation reflectivity, is also available on NAV CANADA's Aviation Weather Web Site (AWWS), from the Flight planning section at www.navcanada.ca/EN/products-and-services/Pages/flight-planning.aspx. Over the next few years, the weather radar network will be improved to offer better images and updates every 6 minutes. During the upgrades, radars will be unavailable and information from neighboring radars will need to be used.

Detailed and real time information from the Canadian Lightning Detection Network (CLDN) is available to the FICs and ACCs that can provide verbal descriptions to pilots.

Figure 1.3 – Environment Canada/DND Weather Radar Network

1.4 IN-FLIGHT METEOROLOGICAL INFORMATION (VOLMET)

In-flight meteorological information (VOLMET) is meteorological information for aircraft in flight, particularly those over the high seas. VOLMET contains airport routine meteorological reports (METARs) and aerodrome forecasts (TAFs) for selected airports and may be provided either by data link (D-VOLMET) or by voice broadcasts on designated frequencies, normally high frequency (HF).

Information on the content, issue times and transmitter frequencies for North Atlantic (NAT) VOLMET broadcasts is given in the *Canada Flight Supplement* CFS, Section D, Radio Navigation and Communications.

**CANADA
PILOT REPORTS****SECTION 2****2.1 GENERAL**

A pilot weather report (PIREP) is a report pertaining to current weather conditions encountered by aircraft in flight. A PIREP is extremely useful to other pilots, forecasters, dispatchers and weather briefers as it provides up-to-the-minute weather information to supplement what is received from meteorological observing stations. In addition, a PIREP is an invaluable data source for aviation meteorologists because it either confirms an existing forecast or highlights the requirement for an amendment. A PIREP may also be the only information available regarding areas between reporting stations, particularly those areas whose topography may produce localized weather phenomena (e.g., hills or expanses of water). Urgent PIREPs are issued for atmospheric conditions that are an immediate hazard for all aviation users.

Pilots are encouraged to file brief reports of weather conditions when giving position reports, especially reports of any significant atmospheric phenomena. They are also encouraged to report conditions that differ significantly from those that were forecast. PIREPs that contain critical information on low clouds, reduced visibility, icing, and convective activities such as wind shear, squall line, turbulence, thunderstorms and cumulonimbus clouds are especially useful. PIREPs of hazardous conditions may trigger the issuance of a SIGMET.

For timely distribution, PIREPs should be filed with a flight information center (FIC) via an enroute frequency or by a toll-free call to an FIC after landing. PIREPs received by flight service personnel are immediately disseminated on meteorological communications circuits and provided to other air traffic service (ATS) units and the Canadian Meteorological Aviation Centres (CMAC).

Controllers, flight service specialists and community airport radio station (CARS) observer/communicators (O/Cs) may request reports from pilots regarding specific weather conditions or weather conditions encountered during enroute, climb-out or approach phases.

SERVICES AND TELEPHONE NUMBERS contain the toll-free FIC telephone numbers. The recommended contents of a PIREP are:

- a. Location and time of phenomena (ident, radial, dist, time)
- b. Altitude
- c. Aircraft type
- d. Cloud (Base, Amount, Top)
- e. Temperature
- f. Wind direction and speed
- g. Turbulence (intensity, type, altitude)
- h. Icing (intensity, type, altitude)
- i. Remarks

**CANADA
PILOT REPORTS**

2.1.1 PIREP Example

EXAMPLE: UACN10 CYXU 032133 YZ UA /OV YXU 090010 /TM 2120 /FL080 /TP PA31 /SK 020BKN040 110OVC /TA -12 /WV 030045 /TB MDT BLO 040 /IC LGT RIME 020-040 /RM NIL TURB CYYZ-CYHM

PIREP EXAMPLE	DECODED EXAMPLE
UACN10	<i>Message Type:</i> Regular PIREP. Urgent PIREPs are encoded as UACN01 or UUA.
CYXU	<i>Issuing office:</i> London FIC.
032133	<i>Date/Time of Issue:</i> 3rd day of the month, at 2133Z.
YZ	<i>FIR:</i> Toronto. If the PIREP extends into an adjacent FIR, both FIRs will be indicated.
UA /OV YXU 090010	<i>Location:</i> London VOR 090° radial, 10 NM. PIREP location will be reported with reference to a NAVAID, airport or geographic coordinates (latitude/longitude).
/TM 2120	<i>Time of PIREP:</i> 2120Z
/FL080	<i>Altitude:</i> 8000 ft ASL. Altitude may also be reported as “DURD” (during descent), “DURC” (during climb) or “UNKN” (unknown).
/TP PA31	<i>Aircraft Type:</i> Piper Navajo (PA31).
/SK 020BK N040 110OVC	<i>Sky Cover:</i> First layer of cloud based at 2000 ft with tops at 4000 ft ASL. Second layer of cloud based at 11,000 ft ASL.
/TA -12	<i>Air Temperature:</i> -12°C.
/WV 030045	<i>Wind Velocity:</i> Wind direction 030° true, wind speed 45 kt. Wind direction reported by pilots in degrees magnetic will subsequently be converted to degrees true for inclusion in PIREP.
/TB MDT BLO 040	<i>Turbulence:</i> Moderate turbulence below 4000 ft ASL.
/IC LGT RIME 020-040	<i>Icing:</i> Light rime icing (in cloud) between 2000 ft ASL and 4000 ft ASL.
/RM NIL TURB CYYZ-CYHM	<i>Remarks:</i> No turbulence encountered between Toronto and Hamilton.

NOTE: Supplementary information for any of the PIREP fields may be included in the remarks (RM) section of the PIREP.

**CANADA
PILOT REPORTS**

2.2 CLEAR AIR TURBULENCE (CAT)

2.2.1 General

Clear air turbulence (CAT) remains a problem for flight operations, particularly above 15,000 feet. The best information available on this phenomenon is still obtained from PIREPs, since a CAT forecast is generalized and cover large areas. All pilots encountering CAT conditions are requested to urgently report the time, location, flight level and intensity (light, moderate, severe, or extreme) of the phenomena to the facility with which they are maintaining radio contact. (See Turbulence Reporting Criteria Table below).

2.2.2 Turbulence Reporting Criteria

INTENSITY	AIRCRAFT REACTION	REACTION INSIDE AIRCRAFT
LIGHT	Turbulence that momentarily causes slight, erratic changes in altitude and/or attitude (pitch, roll, yaw). Report as "light turbulence". OR Turbulence that causes slight, rapid and somewhat rhythmic bumpiness without appreciable changes in altitude or attitude. Report as "light chop".	Occupants may feel a slight strain against seat belts or shoulder straps. Unsecured objects may be displaced slightly. Food service may be conducted and little or no difficulty is encountered in walking.
MODERATE	Turbulence that is similar to light turbulence but of greater intensity. Changes in altitude and/or attitude occur but the aircraft remains in positive control at all times. It usually causes variations in indicated airspeed. Report as "moderate turbulence". OR Turbulence that is similar to light chop but of greater intensity. It causes rapid bumps or jolts without appreciable changes in aircraft altitude or attitude. Report as "moderate chop".	Occupants feel definite strains against seat belts or shoulder straps. Unsecured objects are dislodged. Food service and walking are difficult.
SEVERE	Turbulence that causes large, abrupt changes in altitude and/or attitude. It usually causes large variations in indicated airspeed. Aircraft may be momentarily out of control. Report as "severe turbulence".	Occupants are forced violently against seat belts or shoulder straps. Unsecured objects are tossed about. Food service and walking impossible.

**CANADA
PILOT REPORTS**

The terms “occasional”, “intermittent” and “continuous” are used to describe reported turbulence. Turbulence is considered occasional when it occurs less than 1/3 of the time, intermittent when it occurs 1/3 to 2/3 of the time and continuous when it occurs more than 2/3 of the time.

Pilots should report location(s), time (UTC), intensity, whether in or near clouds, altitude, type of aircraft and, when applicable, the duration of turbulence. Duration may be based on time between two locations or over a single location. All locations should be readily identifiable.

EXAMPLE 1: Over REGINA 1232Z, moderate turbulence, in cloud FL310, B737.

EXAMPLE 2: From 50 NM EAST of WINNIPEG to 30 NM WEST of BRANDON 1210 to 1250Z occasional moderate chop, FL330, AIRBUS 320.

High level turbulence (normally above 15,000 ft ASL) not associated with cumuliform clouds, including thunderstorms, should be reported as CAT preceded by the appropriate intensity or chop type.

2.3 WIND SHEAR (WS)

Intense down drafts, typically associated with thunderstorms, produce strong vertical and horizontal wind shear (WS) components that are a hazard to aviation for aircraft in the approach, landing or takeoff phase of flight. Since ground-based instruments that measure WS have not been installed at Canadian airports, the presence of such conditions can normally be deduced only from PIREPs. Aircraft equipped with Reactive Wind Shear Systems (RWSs) can provide pilots with guidance to conduct a WS escape maneuver. Aircraft with Predictive Wind Shear Systems (PWSs) may allow pilots to avoid or minimize effects of WS (see AIR TRAFFIC CONTROL — INSTRUMENT FLIGHT RULES (IFR) — GENERAL — ATC Clearance).

Aircrew capable of reporting the wind and altitude, both, above and below the shear layer, from Flight Management Systems (FMS) are requested to do so. Pilots without this equipment should report WS by stating the loss or gain of airspeed and the altitude at which it was encountered. Pilots unable to report WS in terms of this specific information should do so in terms of its general effect on the aircraft.

2.4 AIRFRAME ICING

Report icing to ATS and, if operating IFR, request a new routing or altitude if icing will be a hazard. Give your aircraft identification, type, location, time (UTC), intensity of icing, type, altitude or flight level, and indicated airspeed.

The following describes icing and how to report icing conditions:

INTENSITY	ICE ACCUMULATION
Trace	Ice becomes perceptible. Rate of accumulation is slightly greater than the rate of sublimation. It is not hazardous, even though de-icing or anti-icing equipment is not used, unless encountered for an extended period of time (over one hour).
Light	The rate of accumulation may create a problem if flight is prolonged in this environment (over one hour).

**CANADA
PILOT REPORTS**

INTENSITY	ICE ACCUMULATION
Moderate	The rate of accumulation is such that even short encounters become potentially hazardous, and use of de-icing or anti-icing equipment or diversion is necessary.
Severe	The rate of accumulation is such that de-icing or anti-icing equipment fails to reduce or control the hazard. Immediate diversion is necessary.

Icing Types	
Rime ice	Rough, milky opaque ice formed by the instantaneous freezing of small supercooled water droplets.
Clear ice	Glossy, clear, or translucent ice formed by the relatively slow freezing of large supercooled water droplets.
Mixed ice	Both rime and clear icing occurring at the same time.

2.5 VOLCANIC ASH

Flight operations in volcanic ash are hazardous. Pilots may be the first line of volcanic eruption detection in more remote areas. Pilots may be able to provide valuable information about the spread of volcanic ash from an eruption; ash can rapidly rise to altitudes above 60,000 feet and exist at hazardous concentrations up to 1,000 NM from the source. Volcanic ash is not detectable on radar. If an eruption or ash cloud is detected, an urgent PIREP should be filed with the nearest ATS unit.

A volcanic ash forecast chart is produced when required (see MET 3.13).

2.6 PILOT ESTIMATION OF SURFACE WIND

Surface wind direction and speed is information critical to effective pilot decision making for take-off and landing. Where neither wind measuring equipment nor a wind direction indicator is available, the wind direction and speed can be estimated by observing smoke, dust, flags or wind lines on bodies of water.

Pilots on the ground may estimate wind speed and direction by using anything that is free to be moved by the influence of the wind. The descriptions in the Beaufort Wind Scale have been found to be particularly useful and are widely used.

Wind direction can also be estimated accurately by simply facing the wind. Such estimates should only be provided to the nearest eight points (i.e., north, northeast, east) of the compass. The best estimate is obtained by standing in an open area clear of obstructions. Should this not be possible, estimation errors may be so large that pilots using the information should exercise caution. The direction and speed of low-lying clouds can be an indicator of surface winds but should also be used with caution because of the possibility of wind shear near the surface.

Pilots who relay reports of winds based on estimation should ensure that the intended user of the information is aware that it is based on estimation so that appropriate precautions can be taken.

**CANADA
PILOT REPORTS**

BEAUFORT WIND SCALE

Descriptive Term	Beaufort Force	Speed Range (knots)	Knots Average	Specification for estimating wind over Land	Specification for estimating wind over sea (probable wave height in meters*)
Calm	0	Less than 1		Smoke rises vertically	Sea is like a mirror (0)
Light Air	1	1-3	2	Direction of wind shown by smoke	Ripples with the appearance of scales are formed, but without foam crest (0.1)
Light Breeze	2	4-6	5	Wind felt on face; leaves rustle; ordinary vane moved by wind	Small wavelets, still short but more pronounced; crests have a glassy appearance and do not break (0.2 to 0.3)
Gentle Breeze	3	7-10	9	Leaves and small twigs in constant motion; wind extends light flag	Large wavelets; crests begin to break; foam of glassy appearance; perhaps scattered white horses (0.6 to 1)
Moderate Breeze	4	11-16	14	Raises dust and loose paper; small branches are moved	Small waves becoming longer; fairly frequent white horses (1 to 1.5)
Fresh Breeze	5	17-21	19	Small trees in leaf begin to sway; crested wavelets form on inland waters	Moderate waves, taking a more pronounced long form; many white horses are formed, chance of some spray (2 to 2.5)
Strong Breeze	6	22-27	25	Large branches in motion; whistling heard in telephone wires; umbrellas used with difficulty	Large waves begin to form; the white foam crests are more extensive everywhere, probably some spray (3 to 4)
Near Gale	7	28-33	31	Whole trees in motion; inconvenience felt in walking against wind	Sea heaps up and white foam from breaking waves begins to be blown in streaks along the direction of the wind (4 to 5.5)

**CANADA
PILOT REPORTS**

BEAUFORT WIND SCALE (continued)

Descriptive Term	Beaufort Force	Speed Range (knots)	Knots Average	Specification for estimating wind over Land	Specification for estimating wind over sea (probable wave height in meters*)
Gale	8	34-40	37	Breaks twigs off trees; generally impedes progress	Moderately high waves of greater length; edges of crests begin to break into the spindrift; the foam is blown in well-marked streaks along the direction of the wind (5.5 to 7.5)
Strong Gale	9	41-47	44	Slight structural damage occurs to roofing shingles, TV antennae, etc.	High waves; dense streaks of foam along the direction of the wind; crests of waves begin to topple, tumble and roll over; spray may affect visibility (7 to 10)
Storm	10	48-55	52	Seldom experienced inland; trees uprooted; considerable structural damage	Very high waves with long, overhanging crests; the resulting foam, in great patches, is blown in dense white streaks along the direction of the wind; on the whole, the surface of the sea takes on a white appearance; the tumbling of the sea becomes heavy and shock-like; visibility affected (9 to 12.5)
Violent Storm	11	56-63	60	Very rarely experienced; accompanied by widespread damage	Exceptionally high waves (small- and medium-sized ships might be lost to view behind the waves); the sea is completely covered with long patches of foam lying along the direction of the wind; everywhere the edges of the wave crests are blown into froth; visibility affected (11.5 to 16)

**CANADA
PILOT REPORTS****BEAUFORT WIND SCALE (continued)**

Descriptive Term	Beaufort Force	Speed Range (knots)	Knots Average	Specification for estimating wind over Land	Specification for estimating wind over sea (probable wave height in meters*)
Hurricane	12	Above 63			The air is filled with foam and spray; sea completely white with driving spray; visibility seriously affected (16+)

* Wave height is representative of conditions well away from shore and in deep water when winds of that strength have persisted for an extended period of time. The wave height figure does not give the maximum wave height nor does it take into account the effects of swell, air temperature or currents.

**CANADA
APPENDICES**

SECTION 3

3.1 AVIATION FORECASTS AND CHARTS

ITEM AND TYPE DESIGNATOR	TIME ISSUED	TIMES OR PERIODS OF COVERAGE	APPLICABLE LEVEL	REMARKS
Area Forecast Charts (GFA)	Approximately 30 min before the beginning of the forecast period	0000Z, 0600Z, 1200Z, 1800Z. Each new set of GFA charts replaces preceding ones.	Below 24,000 ft	Graphically depicts forecast weather elements affecting flight at a specific time over a particular area.
Aerodrome Forecast (TAF)	Approximately 30 min before the beginning of the validity period	Forecasts are generally issued every 6 hr with validity periods up to a maximum of 30 hr. Issue and update periods may vary. Next issue time is stated at the end of each TAF.	Surface (includes clouds at levels which can be seen from the surface)	The TAF is the forecaster's best judgment of the most probable weather conditions expected to occur at an airport, together with their most probable time of occurrence. It is designed to meet the pre-flight and in-flight requirements of flight operations. They are intended to relate to weather conditions for flight operations within 5 NM of the center of the runway complex, depending on local terrain.
Amended Forecast	Forecasts will be amended when significant changes in ceiling or visibility occur, or when freezing precipitation begins, or is expected to occur, although it was not previously predicted.			
Significant Meteorological Information (SIGMET) WSCN, WCCN, WVCN	A message issued by a meteorological watch office (MWO) to advise pilots of the occurrence or expected occurrence of specified weather phenomena, which may affect the safety of aircraft operations, and the development of those phenomena in time and space.			

**CANADA
APPENDICES**

ITEM AND TYPE DESIGNATOR	TIME ISSUED	TIMES OR PERIODS OF COVERAGE	APPLICABLE LEVEL	REMARKS
Upper Level Wind and Temperature Forecast (FD)	0330Z*	0500-0900Z	3000 feet	Predicts upper winds and temperatures in numerical form at standard levels for a given time period and location.

3.2 AVIATION WEATHER REPORTS

ITEM AND TYPE DESIGNATOR	TIME OBSERVED	REMARKS
Aviation Routine Weather Report MET-AR	Every hour on the hour	Describes actual weather at a specific location and at a specific time as observed from the ground. SPECIs are issued when required. METAR is not available 24 hours a day at all airports.
Pilot Report (PIREP) (UA/UUA)	As reported	Observations of actual conditions reported by pilots during flight.
Volcanic Ash Report (FV)	As required	Describes in graphical format the current and expected ash cloud dispersion and densities at various flight levels.

3.3 WEATHER CHARTS

The international practice is to label the levels in upper level weather charts in hectopascals (hPa) rather than millibars (mb) and this will be increasingly adopted in Canada. Note, however, that one mb equals one hPa.

CANADA APPENDICES

ITEM AND TYPE DESIG- NATOR	TIME OB- SERVED	TIME IS- SUED	REMARKS
Surface Weather Chart	0000Z 0600Z 1200Z 1800Z	2 or 3 hours after obser- vation	Analysis of MSL pressure pattern, surface location of fronts, surface precipitation and obstructions to vision based on reports. Surface pressure patterns can be considered as representative of the atmosphere up to 3000 feet. Weather visible from the surface at any level is included.
Upper Level Chart – ANAL	0000Z 1200Z	Over 3 hours after obser- vation	Charts prepared for following levels: 850 hPa (1500m/5000 feet) 700 hPa (3000m/10,000 feet) 500 hPa (5500m/18,000 feet) 250 hPa (10,400m/34,000 feet) Charts show reported atmospheric conditions at the pressure levels, such as wind speed and direction, temperatures, and moisture content.

3.4 GRAPHIC AREA FORECAST (GFA)

3.4.1 General

The Graphic Area Forecast (GFA) consists of a series of temporally adjusted weather charts, each depicting the most probable meteorological conditions expected to occur at or below 24,000 ft over a given area at a specified time. The GFA is primarily designed to meet general aviation and regional airline requirements for pre-flight planning in Canada.

3.4.2 Issue and Valid Times

Graphic area forecast (GFA) charts are issued four times daily, approximately 30 min before the beginning of the forecast period. The GFA is issued at approximately 2330, 0530, 1130 and 1730 UTC and is valid at 0000, 0600, 1200 and 1800 UTC respectively. Each issue of the GFA consists of six charts; two charts valid at the beginning of the forecast period, two charts valid six hours into the forecast period and the final two charts valid twelve hours into the forecast period. Of the two charts valid at each of the three forecast periods, one chart depicts clouds and weather while the other chart depicts icing, turbulence and freezing level. An IFR outlook for an additional 12-hr period is also included in the comments box of the final clouds and weather chart.

When the GFA is used for times between the chart valid periods, it is necessary to move the synoptic features and to interpolate their position for intermediate times. Use the estimated positions to determine the future position of associated organized weather systems. Each 5 kt of motion indicates a change in position of 30 NM over six hours and the scale in the legend of the chart can be used as a tool. Each panel is a snapshot of a specific future time and does not highlight temporal changes unless specifically stated in the GFA. The existence of convective clouds or

CANADA APPENDICES

morning fog and stratus, and other diurnal phenomenon, often depends on the time span. Always check for the latest nearby observations, which may indicate if features are moving faster or slower than expected, and check for any special comments mentioned in the GFA or for any valid AIRMET that may have amended the GFA. When in doubt, obtain a pre-flight weather briefing in order to use the GFA effectively.

3.4.3 Coverage Area

There are seven distinct GFA areas, covering the entire Canadian domestic airspace, over which Canada is responsible for the provision of air traffic control services. The following map illustrates the GFA coverage areas.

**CANADA
APPENDICES****3.4.4 Units of Measure**

Speeds in the GFA are expressed in knots (kt.) and heights in hundreds of feet. Horizontal visibility is measured in statute miles (SM) and all times are stated in Coordinated Universal Time (UTC). A nautical mile (NM) scale bar is included to assist in determining approximate distances on the chart. All heights are measured above sea level (ASL) unless otherwise noted.

3.4.5 Abbreviations and Symbols

Only standard meteorological abbreviations are used in the GFA. Symbols used in the GFA are consistent with those found on similar meteorological products already described in this document such as significant weather prognostic charts paragraph 3.12.

3.4.6 Layout

Each GFA chart is divided into four parts: Title Box; Legend Box; Comments Box; and Weather Information Section.

Weather Information Section	Title Box
	Legend Box
	Comments Box

3.4.7 Title Box

The Title Box includes the chart name, the issuing office four-letter identification, the name of the graphic area forecast (GFA) region, the chart type, the date and time of issue, and the valid date and time of the chart. The Title Box is found in the upper right corner of the GFA.

In the following example, the Title Box indicates the GFA name (GFACN33) and that it is issued by Canadian Meteorological Centre Network Operations in Montréal (CWAO). The GFA region for the sample chart is ONTARIO-QUÉBEC and the type of chart is clouds and weather. The next section indicates the issue time of the GFA chart, which was September 17, 2014, at 1130Z. The last section states the valid date and time for the GFA chart which, in this example, was September 18, 2014, at 0000Z.

GFACN33 CWAO REGION ONTARIO-QUÉBEC CLOUDS AND WEATHER NUAGES ET TEMPS	
ISSUED AT EMIS A	17/09/2014 1130Z
VLD:	18/09/2014 0000Z

**CANADA
APPENDICES****3.4.8 Legend Box**

The legend box includes weather symbols that may be used in the weather information part of the graphic area forecast (GFA) chart. It also includes a nautical-mile scale bar to facilitate the determination of distances. Symbols used in the GFA are consistent with those used in a significant weather prognostic chart. In the following example, symbols for thunderstorm (TS), ice pellets (PL), freezing rain (FZRA) and freezing drizzle (FZDZ) are indicated in the legend box. These symbols are depicted in red when shown in color.

**3.4.9 Comments Box**

The Comments Box provides information that the weather forecaster considers important (e.g., formation or dissipation of fog, increasing or decreasing visibility). It is also used to describe elements that are difficult to render pictorially or, if added to the depiction, would cause the chart to become cluttered (e.g., light icing). The standard phrases “HGTS ASL UNLESS NOTED” and “TCU, ACC AND CB IMPLY SIG TURBC AND ICE. CB IMPLIES L LVL WS” are also included in the Comments Box.

COMMENTS/COMMENTAIRES	
1. FG/BR DSIPTG AFT 14Z	2. SC CIGS BECMG SCT AFT 15Z
HGTS ASL UNLESS NOTED CB TCU AND ACC IMPLY SIG TURBC AND ICG. CB IMPLIES LLWS	
 Environment Canada Environnement Canada	
IFR OTLK	
IFR CIG/RA/BR S STLAWRC VLY. LCL IFR IN ONSHR/UPSLP NWLY FLO OFF JMSBA AND HSNBA	

In this example, the forecaster has added two comments. The first indicates that the Fog/Mist will dissipate after 1400 UTC. The second comment advises that ceilings will become scattered after 1500 UTC.

The Comments Box of the 12-hr Clouds and Weather GFA chart also includes an IFR outlook for an additional 12-hr period in the lower section of the box. The IFR outlook is always general in nature, indicating the main areas where IFR weather is expected, the cause for the IFR weather and any associated weather hazards. In the example given, IFR conditions caused by low ceilings (CIG), rain (RA) and mist (BR) south of the St. Lawrence Valley are forecast. Also, local IFR con-

**CANADA
APPENDICES**

ditions are forecast because of an onshore (ONSHR) and upslope (UPSLP) northwesterly flow of air from James Bay (JAMSBA) and Hudson's Bay (HSNBA).

For meteorological purposes, the IFR outlook is based on the following:

CATEGORY	CEILING	VISIBILITY
IFR	less than 1000 ft AGL	and/or less than 3 SM
MVFR	between 1000 ft and 3000 ft AGL	and/or between 3 and 5 SM
VFR	more than 3000 ft AGL	and more than 5 SM

In the event that no organized IFR conditions are expected in the outlook period, NIL SIG WX is written in the comment box. Only IFR conditions are included in the IFR outlook of the GFA. Marginal visual flight rules (MVFR) conditions are defined in the table for reference only.

3.4.10 Weather Information

The Weather Information part of the chart depicts either a forecast of the clouds and weather conditions or a forecast of the icing, turbulence and freezing level conditions for a specified time.

CANADA APPENDICES

3.4.11 Clouds and Weather Chart

The Graphic Area Forecast (GFA) Clouds and Weather Chart provides a forecast of cloud layers and/or surface-based phenomena, visibility, weather and obstructions to vision at the valid time of that particular chart. Lines joining points of equal surface pressure (isobars) are depicted at 4-hPa intervals. In addition, relevant synoptic features that are responsible for the portrayed weather are also depicted, with an indication of their speed and direction of movement at the valid time.

- Synoptic Features** — The motion of synoptic features when the speed of movement is forecast to be 5 kt or more will be indicated by an arrow and a speed value. For speeds less than 5 kt, the letters STNR (stationary) are used. A low pressure center moving eastward at 15 kt with an associated cold front moving southeast at 10 kt would be indicated as follows:

CANADA APPENDICES

- b. **Clouds** — The bases and tops of forecast clouds between the surface and 24,000 ft ASL will be indicated on the GFA Clouds and Weather chart. The tops of convective clouds (i.e., TCU, ACC, CB) are indicated, even if they extend above 24,000 ft ASL. Cirrus clouds are not depicted on the chart. The cloud type will be indicated if considered significant; however, convective clouds, such as CU, TCU, ACC and CB, will always be stated if forecast to be present.

A scalloped border, depicted in brown when shown in color, encloses organized areas of clouds where the sky condition is either broken (BKN) or overcast (OVC). An organized area of broken cumulus clouds based at 2000 ft ASL with tops at 8000 ft ASL would be indicated as follows:

Where organized areas of clouds are not forecast and the visibility is expected to be greater than 6 SM, a scalloped border is not used. In these areas, the sky condition is stated using the terms SKC, FEW or SCT. In the following example, unorganized scattered clouds are forecast based at 3000 ft ASL with tops at 5000 ft ASL:

SCT $\frac{50}{30}$

When a forecasted cloud deck contains more than one significant cloud layer, the cloud amount description depends on the space between the layers. When the separation is less than 2000 ft, the descriptor represents the summation amount across all the layers, and the term LYRS is included immediately after it. When the separation is 2000 ft or greater, each

CANADA
APPENDICES

layer is stated, with its own descriptor that applies only to that layer. The bases and tops of each layer are indicated. For instance, a scattered layer of cumulus cloud based at 3000 ft ASL with tops at 5000 ft ASL and a higher overcast layer of altostratus cloud based at 10,000 ft ASL with tops at 13,000 ft ASL would be indicated as follows:

All heights are indicated in hundreds of feet ASL (2 means 200 ft, 45 means 4500 ft, etc.) unless otherwise specified. Above ground level heights are indicated by the abbreviation CIG and AGL (e.g., CIGS 5-10 AGL). A note to this effect is included in the Comments Box in the lower right hand corner of the chart.

- c. **Surface-based Layers** — The vertical visibility into surface-based layers is measured in hundreds of feet AGL. Local obscured ceilings with a vertical visibility of between 300 and 500 ft AGL would be indicated as follows:

LCL CIG 3-5

AGL

- d. **Visibility** — The forecast visibility is measured in statute miles. When the visibility is expected to be greater than 6 SM, it is indicated as P6SM. A forecast visibility that is expected to vary between 2 and 4 SM with light rain showers would be indicated as:

2-4SM – SHSN

- e. **Weather and Obstructions to Vision** — Forecast weather is always included immediately after the visibility. Obstructions to vision are only mentioned when the visibility is forecast to be 6 SM or less (e.g. 2-4SM – RA BR). Only standard abbreviations are used to describe weather and obstructions to vision. Areas of showery or intermittent precipitation are shown as hatched areas enclosed by a dashed green line. Areas of continuous precipitation are shown as stippled areas enclosed by a solid green line. Areas of obstruction to vision not associated with precipitation, where visibility is 6 SM or less, are enclosed by a dashed orange line. Areas of freezing precipitation are depicted in red and enclosed by a solid red line.

**CANADA
APPENDICES**

Weather and obstructions to vision in the GFA may include spatial qualifiers, which describe the coverage of the depicted meteorological phenomena.

Convective Clouds and Showers

Abbreviation	Description	Spatial Coverage
ISOL	Isolated	25% or less
OCNL	Occasional	26–50%
FRQ	Frequent	Greater than 50%

Non-convective clouds and precipitation, low stratus ceilings, precipitation ceilings, icing, turbulence, and restrictions to visibility:

Abbreviation	Description	Spatial Coverage
LCL	Local	25% or less
PTCHY	Patchy	26–50%
XTNSV	Extensive	Greater than 50%

- f. **Isobars** — Isobars, which are lines joining points of equal mean sea level (MSL) pressure, are depicted on the GFA clouds and weather chart. Isobars are drawn at 4-hPa intervals from a reference value of 1000 hPa.

CANADA APPENDICES

- g. **Surface Winds** — The speed and direction of forecast surface winds with a sustained speed of at least 20 kt are indicated by wind barbs and an associated wind speed value. When accompanied by strong gusts, mean sustained winds of less than 20 kt may also be included, at the forecaster's discretion, if moderate mechanical turbulence is expected to occur as a result of the wind gusts. Wind gusts are indicated by the letter "G", followed by the peak gust speed in knots. In the following example, the surface wind is forecast to be from the west (270° true) with a speed of 25 kt and a peak gust speed of 35 kt.

3.4.12 Icing, Turbulence and Freezing Level Chart

CANADA APPENDICES

The Graphic Area Forecast (GFA) Icing, Turbulence and Freezing Level Chart depicts forecast areas of icing and turbulence as well as the expected freezing level at a specific time. Included on the chart are the type, intensity, bases and tops for each icing and turbulence area. Surface synoptic features such as fronts and pressure centers are also shown. This chart is to be used in conjunction with the associated GFA Clouds and Weather chart issued for the same period of validity.

- a. **Icing** — Depicted in blue when shown in color and indicated whenever moderate or severe icing is forecast for the coverage area. The bases and tops of each icing layer, measured in hundreds of feet above mean sea level, as well as the type of icing [e.g., “RIME,” “MX” (mixed), “CLR” (clear)] will be indicated. Areas of light icing are described in the comments box. An area of moderate mixed icing based at 2000 ft ASL with a top of 13,000 ft ASL would be indicated as follows:

If icing is expected to be present during only part of the forecast period covered by the chart, the time of occurrence of the icing is indicated in the Comments Box.

Areas of severe icing are indicated with a denser stippling. The following is an example of an area of severe icing contained within an area of moderate icing:

- b. **Turbulence** — Depicted in red when shown in color and indicated whenever moderate or severe turbulence is forecast for the coverage area. The base and top of each turbulence layer is measured in hundreds of feet above sea level except for surface-based turbulence, which is measured in AGL. An abbreviation indicating the cause of the turbulence will be included: mechanical turbulence, low-level wind shear, lee/mountain waves, a significant low-level jet or in clear air, will be indicated as MECH, L LVL WS, LEE WV, L LVL JET or

CANADA
APPENDICES

CAT, respectively. The following example indicates an area of moderate Clear Air Turbulence (CAT) based at 18,000 ft ASL with a top at 26,000 ft ASL.

Severe turbulence is depicted with a higher density of hatching. The following example shows an area of severe turbulence surrounded by a larger area of moderate turbulence:

When separate areas of turbulence are occurring at different altitudes, the lower level is shown with hatching that slants upward to the right, while the higher level is depicted with hatching that slants downward to the right, as indicated below:

- c. **Freezing Level** — Freezing level contours are indicated on a GFA by dashed lines. The height of the freezing level is indicated to the nearest multiple of 2500 ft using the standard heights in hundreds of feet ASL (e.g. SFC, 25, 50, 75, 100, meaning, surface, 2500, 5000, 7500, 10,000). When more than one freezing level is forecast, only the lowest level needs to be indicated, unless meteorological conditions are expected to be relevant to aviation safety

CANADA APPENDICES

(e.g. freezing precipitation aloft). An above freezing layer (AFL) is indicated by a closed area as shown below:

Temporal changes in the freezing level, when significant, are indicated in the comments box of the chart, as in the following example:

FZLVL 20 LOWERING TO SFC AFT 03Z

- d. **Low level jet (L LVL JET)** — Included on the GFA icing, turbulence and freezing level chart when it is expected to have a peak core speed of 50 kt or more. It may be included at speeds between 35 and 45 kt when significant associated turbulence or shear is expected. An L LVL JET is depicted as follows, with the wind being in the direction of the arrow and the speed shown being the maximum expected wind speed:

In general, L LVL JETs are not included if they are above 6000 ft ASL, except as required over higher terrain. The height of the jet is not indicated. In many cases, there may be associated turbulence, as shown in the example below:

3.4.13 Graphic Area Forecast (GFA) Amendments

Once issued, a SIGMET or AIRMET message automatically amends the current and relevant GFA. The remark (RMK) found in the National version of those messages indicates the GFA region(s) to which the SIGMET or AIRMET applies.

CANADA APPENDICES

3.4.14 Graphic Area Forecast (GFA) Corrections

A correction to a GFA is issued for the following events:

- a. The occurrence of any unforecast weather phenomena that do not require an AIRMET (i.e. they are below the AIRMET criteria threshold) or any other unforecast weather phenomena that, according to the forecaster, should be depicted in the GFA.
- b. Forecast weather phenomena in the GFA fail to occur, in which case the weather phenomena that are no longer occurring or no longer expected to occur are removed.
- c. A significant error was made in a GFA chart. A significant error is one which, if uncorrected, would result in an erroneous interpretation of the GFA and create a potential hazard to aviation.

For detailed guidance on GFA correction, refer to the *Manual of Standards and Procedures for Aviation Weather Forecasts* (MANAIR), Appendix C (not published herein). Information about the nature of the correction made to the chart is included in the comments box.

When re-issued, the correction code “CCA” is added to the first line of the Title Box to indicate the first correction, “CCB” for the second, “CCC” for the third, etc.

GFACN33 CWAQ CCA REGION ONTARIO-QUEBEC CLOUDS AND WEATHER NUAGES ET TEMPS	
ISSUED AT EMIS A	17/09/2014 1211Z
VLD:	17/09/2014 1200Z

3.5 AIRMET

3.5.1 Definition

An information message issued by a Meteorological Watch Office (MWO) to advise pilots of the occurrence or expected occurrence of weather phenomena, which may affect the safety of aircraft operations and which were not already included in the GFA. The message shall describe potentially hazardous weather conditions up to and including 24,000 ft (FL240).

3.5.2 Issuance Criteria

AIRMETs are issued when the following criteria occur or are expected to occur and were not forecast in the GFA and a SIGMET is not warranted. The abbreviations shown in all capitals will be used as described below.

**CANADA
APPENDICES**

- a. Surface wind speed – Widespread mean surface wind speed above 30 kt is indicated by SFC WSPD (along with details of the wind speed or wind speed range and units).
- b. Surface visibility and/or cloud:
 - 1. Widespread areas affected by reduced visibility of less than 3 SM (5000m), including weather phenomena causing reduced visibility indicated by SFC VIS (along with details of the visibility or visibility range and the weather phenomena or combinations thereof);
 - 2. Widespread areas of broken or overcast cloud with height of base less than 1000 ft (300m) AGL indicated by BKN CLD or OVC CLD (along with details of the height or height range of the base, top and units).
- c. Thunderstorms and/or towering cumulus:
 - 1. Isolated thunderstorms ISOL TS;
 - 2. Occasional thunderstorms OCNL TS;
 - 3. Isolated thunderstorm with hail ISOL TSGR;
 - 4. Occasional thunderstorms with hail OCNL TSGR;
 - 5. Isolated towering cumulus ISOL TCU;
 - 6. Occasional towering cumulus OCNL TCU;
 - 7. Frequent towering cumulus FRQ TCU;
 - 8. Occasional towering cumulus and isolated thunderstorms OCNL TCU ISOL TS;
 - 9. Frequent towering cumulus and isolated thunderstorms FRQ TCU ISOL TS;
 - 10. Occasional towering cumulus and isolated thunderstorms with hail OCNL TCU ISOL TS GR;
 - 11. Frequent towering cumulus and isolated thunderstorms with hail FRQ TCU ISOL TSGR.
- d. Turbulence — moderate turbulence (except for turbulence in convective clouds) MOD TURB;
- e. Icing — moderate icing (except for icing in convective clouds) MOD ICE;
- f. Mountain wave — moderate mountain wave MOD MTW.

An AIRMET will only be issued for one of these criteria at any time. If more than one criterion occurs then more than one AIRMET will be issued.

An isolated (ISOL) phenomena consists of individual features which affect, or are forecast to affect, an area with a maximum spatial coverage of 25% or less of the area concerned (at a fixed time or during the period of validity).

An occasional (OCNL) phenomenon consists of well separated features which affect, or are forecast to affect, an area with a maximum spatial coverage of between 25% and 50% of the area concerned (at a fixed time or during the period of validity).

CANADA APPENDICES

Frequent (FRQ) coverage indicates an area of towering cumulus (TCU) within which there is little or no separation between adjacent clouds and with a maximum spatial coverage greater than 50% of the area affected, or forecast to be affected, by the phenomenon (at a fixed time or during the period of validity).

3.5.3 Coordinate Points

The ICAO AIRMET message describes a coordinate point using only latitude and longitude.

The national AIRMET message describes a coordinate point using latitude and longitude. In addition, an equivalent description is given in terms of direction and distance from an aviation reference site.

There are 2 exceptions to this rule for the national AIRMET:

- Any coordinate point located within Gander Oceanic FIR will be described in latitude and longitude only.
- Any coordinate point north of N72°00' will be described with respect to an aviation reference site only if it is within a 90 NM radius of that site. Otherwise the coordinate point will be represented in latitude and longitude only. This is due to the sparse number of aviation reference sites in northern Canada.

The useable reference points will be a subset of airports listed in the CFS. A complete list will be included in MANAIR.

3.5.4 Rules for the Use of Letters

All 8 FIRs share 25 letters of the alphabet (T is used only for tests).

The letter used cannot currently be in service in any other FIR and has to have been retired for a minimum of 24 hrs, otherwise the next letter is used. In addition, the same letter cannot be used for widely separated occurrences of the same phenomenon, even within a single FIR.

The letter Z will wrap back to A if necessary.

If all letters are unavailable, the letter that has had the longest retirement will be re-used.

The letter attributed to a bulletin will not change during its life span (updates and cancellation).

AIRMET messages do not share the same alphabet with WS (SIGMET). The letter A may be used simultaneously in both a WS (or WC or WV) and a WA.

3.5.5 Rules for the Use of Numbers

- Numbering of an event (as defined by the unique use of a letter in a FIR) begins at 1 (i.e. B1).
- The number is incremented by 1 when updating a message, including cancellation.
- The sequence number shall correspond with the number of messages issued for an FIR since 0000Z on the day concerned.
- The numbering is thus reset at 0000Z (messages are not updated at 0000Z for the sole purpose of resetting the number).

**CANADA
APPENDICES****3.5.6 Validity**

The period of validity of an AIRMET is 4 hr and it may be issued up to 4 hr prior to the start of the validity period (i.e. expected time of occurrence of the phenomenon).

In the case of an AIRMET for an ongoing phenomenon, the date/time group indicating the start of the AIRMET period will be rounded back to 5 min from the filing time (date/time group in the WMO heading).

In the case of an AIRMET for an expected phenomenon (forecast event), the beginning of the validity period will be the time of the expected commencement (occurrence) of the phenomenon.

An AIRMET for an expected phenomenon (forecast event) is issued only for the first appearance of that event in Canadian airspace (e.g., moving in from the U.S. or onset inside a Canadian FIR). A phenomenon moving from one Canadian FIR to another is treated as an ongoing phenomenon. No forecast event AIRMET messages would be sent for the second FIR.

3.5.7 Location of the Phenomenon

The location of the phenomenon is depicted as an area using coordinate points. The description always begins with the abbreviation WI (within) and the area can be described as a circle, a line or a polygon. Distances are in nautical miles and direction is to one of the eight (8) points of compass (octants). The following examples show the ICAO format first and followed by the national format.

Circle**ICAO:**

WI 45 NM OF N4643 W07345

National:

WI 45 NM OF /N4643 W07345/75 N CYUL

Plain language explanation of the national format: within 45 NM of a point, with specified latitude and longitude, that is 75 NM north of Montréal/Pierre Elliott Trudeau International Airport.

Line**ICAO:**

WI 45 NM OF LINE N4459 W07304 – N4855 W07253 – N5256 W06904

National:

WI 45 NM OF LINE /N4459 W07304/45 SE CYUL – /N4855 W07253/30 NW CYRJ – /N5256 W06904/75 W CYWK

Plain language explanation of the national format: within 45 NM of a line from a point 45 NM southeast of Montréal/ Pierre Elliott Trudeau International Airport to a point 30 NM northwest of the Roberval Airport, followed by a point 75 NM west of Wabush Airport with the latitude and longitude of each point being specified.

Polygon**ICAO:**

**CANADA
APPENDICES**

WI N4502 W07345 – N4907

W07331 – N5345 W06943 – N5256

W06758 – N4848 W07149 – N4508

W07206 - N4502 W07345

National:

WI /N4502 W07345/25 SW CYUL – /N4907 W07331/60 SE CYMT – /N5345

W06943/150 E CYAH – /N5256 W06758/45 W CYWK – /N4848 W07149/25 NE CYRJ – /N4508
W07206/25 SW CYSC – /N4502 W07345/25 SW CYUL

Plain language explanation of the national format: within an area bounded by points that are 25 NM southwest of Montréal/Pierre Elliott Trudeau International Airport; 60 NM southeast of Chibougamau/Chapais Airport; 150 NM east of La Grande-4 Airport; 45 NM west of Wabush Airport; 25 NM northeast of Roberval Airport and 25 NM southwest of Sherbrooke, then back to a point 25 NM southwest of Montréal/Pierre Elliott Trudeau International Airport. The latitude and longitude of each point being specified.

NOTE: The polygon must be closed. The last coordinate is a repeat of the first one.

3.5.8 Flight Level and Extent

The location and extent of the phenomenon in the vertical is given by one or more of the following:

- Reporting a layer – FL<nnn/nnn>, where the lower level is reported first; this is used particularly in reporting turbulence and icing.
- Reporting a layer with reference to one FL using surface (SFC).
- Reporting the level of the tops of the thunderstorm (TS) and/or towering cumulus (TCU) clouds using the abbreviation TOP.

3.5.9 Movement or Expected Movement

Direction of movement is given with reference to one of the sixteen (16) points of compass (radials). Speed is given in kt (KT). The abbreviation QS or quasi stationary is used if no significant movement is expected.

3.5.10 Change in Intensity

The expected evolution of a phenomenon's intensity is indicated by one of the following abbreviations:

INTSF — intensifying

WKN — weakening

NC — no change

**CANADA
APPENDICES****3.5.11 Remark**

The remark (RMK) is found only in the national AIRMET message. It begins on a new line. The purpose is to allow additional information of national interest to be conveyed in the AIRMET message. Items listed in the remark line will be separated by a forward slash (/). The remark always includes the GFA region(s) that the AIRMET applies to (see Example 1 in paragraph 3.5.16). The remark may also include:

- a. Cross-references to AIRMET messages when a phenomenon straddles one or several FIR boundaries (see Example 1 in paragraph 3.5.16).
- b. For a phenomenon that has moved out of an FIR, the cancelled AIRMET message will refer to the continuing AIRMET message in neighboring FIR(s) within Canada's area of responsibility.

3.5.12 Updated AIRMET

An updated AIRMET, when issued, automatically replaces the previous AIRMET in the same series (i.e. the previous AIRMET with the same letter). An AIRMET must be updated every 4 hr (from date/time group in the WMO heading).

However, a forecaster may update an AIRMET at any time if he/she considers it necessary.

3.5.13 Cancellation

An AIRMET must be cancelled when, during its validity period:

- a. the phenomenon for which the AIRMET had been issued is no longer occurring or no longer expected to occur (forecast AIRMET);
- b. the phenomenon for which the AIRMET had been issued strengthens such that a SIGMET is now required; or
- c. the new issue of the GFA has been transmitted and now includes the phenomenon.

An AIRMET does not cancel itself automatically at the end of its validity period. A cancellation AIRMET with the abbreviation CNCL must be issued.

3.5.14 Test AIRMET

There may be occasions when test AIRMET messages are transmitted by the meteorological watch office (MWO). The test AIRMET messages will be identifiable by the letter T in the alphanumeric sequence (see – Rules for the Use of Letters). Additionally, the statement “**THIS IS A TEST**” will be added at the beginning and end of the message.

3.6 SIGNIFICANT METEOROLOGICAL INFORMATION (SIGMET)

3.6.1 Definition

Information message issued by a meteorological watch office (MWO) to advise pilots of the occurrence or expected occurrence of specified weather phenomena, which may affect the safety of aircraft operations, and the development of those phenomena in time and space.

3.6.2 Issuance Criteria

SIGMET are issued in response to the following criteria with abbreviations shown in all capital letters:

- a. Thunderstorms:
 1. Frequent FRQ TS
 2. Frequent with hail FRQ TSGR
 3. Frequent with hail and possible tornado/waterspout FRQ TSGR POSS +FC
 4. Frequent with hail and tornado/waterspout FRQ TSGR +FC
 5. Squall line SQLN TS
 6. Squall line with hail SQLN TSGR
 7. Squall line with possible tornado/waterspout SQLN TSGR POSS +FC
 8. Squall line with tornado/waterspout SQLN TSGR +FC
- b. Severe turbulence SEV TURB
- c. Severe icing SEV ICE
- d. Severe icing due to freezing rain SEV ICE (FZRA)
- e. Severe mountain wave SEV MTW
- f. Low level wind shear L LVL WS
- g. Heavy duststorm HVY DS
- h. Heavy sandstorm HVY SS
- i. Radioactive cloud RDOACT CLD
- j. Volcanic ash VA
- k. Tropical cyclone TC

NOTE:

CANADA APPENDICES

1. *A squall line is defined as thunderstorms along a line with little or no space between the individual clouds.*
2. *Severe (SEV) turbulence (TURB) refers only to:*
 - (a) *Low-level turbulence associated with strong surface winds;*
 - (b) *Rotor streaming;*
 - (c) *Turbulence whether in cloud or not in cloud (i.e. clear air turbulence [CAT]) near jet streams.*
3. *TS implies severe icing and turbulence therefore separate SIGMET for these phenomenon are not issued in connection with convective clouds.*
4. *SIGMET will only be issued for one of these criteria at any time. If more than one criterion occurs then more than one SIGMET will be issued.*
5. *Frequent (FRQ) coverage indicates an area of thunderstorms within which there is little or no separation between adjacent thunderstorms and with a maximum spatial coverage greater than 50% of the area affected or forecast to be affected by the phenomenon (at a fixed time or during the period of validity).*
6. *For radioactive cloud SIGMET bulletins, only a circle shape is to be used for element 5 "location." A radius of up to 15 NM from the source and a vertical extent from surface (SFC) to the upper limit of the flight information region (FIR) is to be applied. Only stationary (STNR) is to be used for expected movement.*

3.6.3 Coordinate Points

The ICAO SIGMET message describes a coordinate point using latitude and longitude only.

The national SIGMET message describes a coordinate point using latitude and longitude. However, in addition, an equivalent description is also given in terms of direction and distance from an aviation reference site.

There are 2 exceptions to the rule for the national SIGMET:

- a. Any coordinate point located within Gander Oceanic FIR will be described in latitude and longitude only.
- b. Any coordinate point north of N72°00' will be described with respect to an aviation reference site only if it is within a 90 NM radius of that site. Otherwise the coordinate point will be represented in latitude and longitude only. This is due to the sparse number of aviation reference sites in northern Canada.

The useable reference sites will be a subset of airports listed in the CFS and the closest airport(s) to the area of the phenomenon are used. A complete list is included in the *Manual of Standards and Procedures for Aviation Weather Forecasts (MANAIR)*.

3.6.4 Rules for the Use of Letters

All 8 FIRs share 25 letters of the alphabet (T is used only for tests).

CANADA APPENDICES

The letter used cannot currently be in service in any other FIR and has to have been retired for a minimum of 24 hrs, otherwise the next letter is used. In addition, the same letter cannot be used for widely separated occurrences of the same phenomenon, even within a single FIR.

The letter Z will wrap back to A if necessary.

If all letters are unavailable, the letter that has had the longest retirement will be re-used.

The letter attributed to a bulletin will not change during its life span (updates and cancellation).

SIGMET messages do not share the alphabet with WA (AIRMET). The letter A may be used simultaneously in both a WS (or WC or WV) and a WA.

3.6.5 Rules for the Use of Numbers

- Numbering of an event (as defined by the unique use of a letter in a FIR) begins at 1 (i.e. B1).
- Number incremented by 1 when updating a message, including cancellation.
- The sequence number shall correspond with the number of messages issued for a FIR since 0000Z on the day concerned.
- The numbering is thus reset at 0000Z (messages are not updated at 0000Z for the sole purpose of resetting the number).

3.6.6 Validity

The period of validity of a WS SIGMET is 4 hr and it may be issued up to 4 hr prior to the commencement of the phenomenon in the corresponding FIR. There is an exception for volcanic ash and tropical storm SIGMETs which are valid for 6 hr and may be issued up to 12 hr before they enter the corresponding FIR.

In the case of a SIGMET for an ongoing phenomenon, the date/time group indicating the start of the SIGMET period will be rounded back to 5 min from the filing time (date/time group in the WMO heading).

In the case of a SIGMET for an expected phenomenon (forecast event), the beginning of the validity period will be the time of the expected commencement (occurrence) of the phenomenon.

Any SIGMET for an expected phenomenon (forecast event) is issued only for the first appearance of an event in Canadian airspace (e.g., moving in from the U.S. or onset inside a Canadian FIR). A phenomenon moving from one Canadian FIR to another is treated as an ongoing phenomenon. No forecast event SIGMET messages would be sent for the second FIR.

3.6.7 Location of the Phenomenon

The location of the phenomenon is depicted as an area using coordinate points. The description always begins with the abbreviation WI (within) and the area can be described as a circle, a line or a polygon. Distances are in NM and direction is to one of the eight (8) points of compass (octants). The following examples show the ICAO format first and the national format second, see paragraph 3.5.7.

Circle

W07206/25 SW CYSC – /N4502 W07345/25 SW CYUL

NOTE: Tropical cyclone and volcanic ash SIGMETs also describe the affected location at the end of the forecast period.

3.6.8 Flight Level and Extent

The location and extent of the phenomenon in the vertical is given by one or more of the following:

- a. Reporting a layer – FL<nnn/nnn>, where the lower level is reported first; this is used particularly in reporting turbulence and icing.
- b. Reporting a layer with reference to one FL using surface (SFC).
- c. Reporting the level of the tops of the thunderstorms (TS) using the abbreviation TOP.

3.6.9 Movement or Expected Movement

Direction of movement is given with reference to one of the sixteen (16) points of compass (radials). Speed is given in knots. The abbreviation STNR (stationary) is used if no significant movement is expected.

**CANADA
APPENDICES****3.6.10 Change in Intensity**

The expected evolution of a phenomenon's intensity is indicated by one of the following abbreviations:

INTSF — intensifying

WKN — weakening

NC — no change

3.6.11 Remarks

The remark (RMK) is found only in the national SIGMET message. It begins on a new line. The purpose is to allow additional information of national interest to be conveyed in the SIGMET message. Items listed in the remark line will be separated by a forward slash (/). The remark always includes the GFA region(s) that the SIGMET message applies to (see Example 1 in paragraph 3.6.16). The remark may also include:

- a. Cross-references to SIGMET messages when a phenomenon straddles one or several FIR boundaries (see Example 1 in paragraph 3.6.16).
- b. For a phenomenon that has moved out of an FIR, the cancelled SIGMET message will refer to the continuing SIGMET message in neighboring FIR(s) within Canada's area of responsibility (see Example 2 in paragraph 3.6.16).

3.6.12 Updated Significant Meteorological Information (SIGMET)

An updated SIGMET, when issued, automatically replaces the previous SIGMET in the same series (i.e. the previous SIGMET with the same letter).

A WS SIGMET must be updated every 4 hr (from date/time group in the WMO heading).

A WV and a WC SIGMET must be updated every 6 hr (from date/time group in the WMO heading).

However, a forecaster may update a SIGMET at any time if he/she considers it necessary.

3.6.13 Cancellation

If, during the validity period of a SIGMET, the phenomenon for which the SIGMET had been issued is no longer occurring or no longer expected to occur, this SIGMET should be cancelled by the issuing meteorological watch office (MWO). A cancellation SIGMET will be issued and will include the abbreviation CNCL.

3.6.14 Test Significant Meteorological Information (SIGMET) Message

There may be occasions when test SIGMET messages are transmitted by the MWO. The test SIGMET messages will be identifiable by the letter T in the alphanumeric sequence. Additionally, the statement **"THIS IS A TEST"** will be added at the beginning and end of the message.

CANADA APPENDICES

3.7 AERODROME FORECAST (TAF) LOCATIONS

NOTE: The above chart is incomplete and may be out of date. Pilots should consult the current flight publications and NOTAM to confirm TAF availability.

3.7.1 General

TAF is the international meteorological code for an airport forecast, which is a description of the most probable weather conditions expected to occur at an airport, together with their most probable time of occurrence. It is designed to meet the preflight and in-flight requirements of flight operations. The abbreviations of expected weather conditions will follow the same form and order of the METAR reports (see paragraph 3.8), and will have the same meaning.

In normal situations, an observation is considered representative of the specific weather conditions at the airport if it is taken within 1.6 NM (3km) of the geometric center of the runway com-

CANADA APPENDICES

plex. TAFs are intended to relate to weather conditions for flight operations within 5 NM of the center of the runway complex, depending on local terrain. Significant weather conditions, such as thunderstorms, within 5 to 10 NM of the airport are also included. A regular and complete observation program that meets Transport Canada (TC) standards for METARs and airport special meteorological reports (SPECI) is a prerequisite for the production of a TAF.

TAFs will also be disseminated in ICAO [International Civil Aviation Organization] meteorological information exchange model (IWXXM) geography markup language (GML) form. The technical specifications for IWXXM are contained in the *Manual on Codes* (WMO [World Meteorological Organization]-No. 306), Volume I.3, Part D. Guidance on the implementation of IWXXM is provided in the *Manual on the ICAO Meteorological Information Exchange Model* (Doc 10003).

Airport advisories are identified by the word “ADVISORY” appearing after the date/time group, followed by one of the qualifying reasons listed below. Advisories are formatted in the same manner as the TAF.

OFFSITE — The advisory is based on an observation that is not taken at or near the airport. “OFFSITE” is added after the word “ADVISORY,” followed by one space, if an observation is not considered representative. It is intended to indicate to the users that the observations do not necessarily reflect the actual conditions at the airport.

OBS INCOMPLETE or NO SPECI — The advisory is based on incomplete data, either because the observations could not be completed or the airport does not have an ongoing weather watch in order to produce special weather reports (SPECI). “OBS INCOMPLETE” or “NO SPECI” shall be added after the word “ADVISORY”, followed by one space.

3.7.2 National Variations

As with the METAR code, even though TAF is an international code, there are national variations. For example, “CAVOK” is not authorized for use in Canadian TAFs, while “RMK” is used but is not part of the international code. A detailed account of the differences that Canada has filed with the World Meteorological Organization (WMO) may be found in the WMO Manual on Codes, Volume II, Regional Codes and National Coding Practices (Doc. 306). (See MET 1.1.7 for ordering information and MET 1.1.8 for differences from ICAO Annex 3.)

3.7.3 Sample Message

- a. *Sample Message Decoded:* Aerodrome Forecast; Saskatoon, Saskatchewan; issued on the 28th day of the month at 1139Z; covers the period from the 28th day of the month at 1200Z to the 29th day of the month at 1200Z; surface wind 240 degrees true at 10 kt, gusting to 25 kt; wind shear is forecast to exist in the layer from the surface to 1100 ft AGL, with the wind at the shear height of 270 degrees true at 50 kt; forecast prevailing visibility is 3 SM in light snow; forecast cloud layers are broken at 1000 ft and overcast at 4000 ft; between 1800 and 0100Z there will be a temporary change to the prevailing visibility to 1 1/2 SM in light snow

CANADA APPENDICES

and moderate blowing snow with a broken cloud layer at 800 ft; there is a 30% probability between 2000 and 2200Z that the prevailing visibility will be 1/2 SM in moderate snow and create an obscuring phenomena resulting in a vertical visibility of 500 ft; at 0130Z there will be a permanent change, the wind is forecast to be 280 degrees true at 10 kt with a prevailing visibility of 5 SM in light snow and a broken cloud layer at 2000 ft; between 0600 and 0800Z there will be a gradual change in the weather to calm winds and a forecast visibility greater than 6 SM, and the sky will be clear of clouds;

Remarks: the next routine airport forecast for this site will be issued by 1800Z on the 28th day.

- b. *Report Type*: The code name "TAF" is given in the first line of text. It may be followed by "AMD" for amended or corrected forecasts.
- c. *Location Indicator*: A four-letter ICAO station indicator, is used as in METARs.
- d. *Date/Time of Origin*: As with the METAR format, the date (day of the month) and time (UTC) of origin are included in all forecasts. TAFs are issued approximately 20 minutes before the validity period. Some forecasts have update cycles as frequent as every three hours; however, the next issue time will always be indicated in the "Remarks" section.
- e. *Period of Validity*: The period of validity for the TAF is indicated by two four-digit date/time groups; the first four-digit group indicates the start date and time of the TAF, and the second four-digit group indicates the end date and time of the TAF. A TAF is considered to be valid from the moment it is issued (e.g. a TAF with an indicated period of validity from 1100Z to 2300Z that was issued at 1040Z is considered to be valid from 1040Z) until it is amended; until the next scheduled TAF for the same airport is issued; or until the period of validity ends and no new TAF has been issued. The maximum period for a TAF is 30 hr; however, some TAFs have staggered issue times and more frequent update cycles, which will affect their periods of validity.
- f. *Wind*: This group forecasts the 2-minute mean wind direction and speed to the nearest 10 degrees true, and speed to the nearest whole knot. KT is used to indicate the speed units. If the maximum gust speed is forecast to exceed the mean speed by 10 knots or more, the letter G and the value of the gust speed, in knots, is added between the mean wind and the units indicator (KT). "VRB" is normally coded for variable direction only if the wind speed is 3 knots or less; however, it may also be coded with higher speeds when it is impossible to forecast a single direction (e.g., when a thunderstorm passes). A north wind of 20 knots would be coded as 36020KT, while calm wind is coded as "00000KT".
- g. *Low Level Wind Shear*: This group is used if the forecaster has strong evidence to expect significant, non-convective wind shear which could adversely affect aircraft operation within 1500 feet AGL over the airport. The height of the top of the shear layer (in hundreds of feet AGL) is given, followed by the forecast wind speed and direction at that height.

While the main effect of turbulence is related to erratic changes in altitude or attitude of the aircraft, or both, the main effect of wind shear is the rapid gain or, more critical, loss of air-speed. Therefore, for forecasting purposes, any cases of strong, non-convective low level wind shear within 1500 feet AGL will be labeled as "WS".

CANADA APPENDICES

To a large extent, wind shear is an element that, for the time being, cannot be satisfactorily observed from the ground. As a result, aircraft observations and radiosonde reports represent the only available evidence.

However the following guidelines are used to establish whether significant non-convective wind shear hazardous to aircraft exists:

1. vector magnitude exceeding 25 knots within 500 feet AGL;
 2. vector magnitude exceeding 40 knots within 1000 feet AGL;
 3. vector magnitude exceeding 50 knots within 1500 feet AGL;
 4. a pilot report of loss or gain of indicated airspeed of 20 knots or more within 1500 feet AGL.
- h. *Prevailing Visibility:* The horizontal prevailing visibility is indicated in statute miles and fractions up to 3 SM, then in whole miles up to 6 SM. Visibilities greater than 6 SM are indicated as P6SM. The letters "SM" are added, without a space, to each forecast visibility, to identify the unit.
- i. *Significant Weather:* Forecast significant weather may be decoded using the list of significant weather given in the "WMO Code, Table 4678" (MET 3.8.3). Intensity and proximity qualifiers, descriptors, precipitation, obscuration and other phenomena are included as required. A maximum of three significant weather groups is allowed per forecast period. If more than one group is used, they are considered one entity. When one of the significant weather groups is forecast to change, all the significant weather groups that will apply after the change are indicated following the change group. Details on the specific effects of change groups on significant weather will be addressed under the change group headings.
- NOTE: The meaning of the proximity qualifier, vicinity (VC), in the TAF code differs slightly from that in the METAR. In the METAR code, "VC" means elements observed within 5 miles, but not at the station. In the TAF code, "VC" means between 5 and 10 NM from the center of the runway complex.*
- j. *Sky Condition:* Sky condition is decoded as in a METAR. Possible codes for sky cover amounts are SKC, FEW, SCT, BKN, OVC and VV. In case of a significant change in a cloud layer, as forecast using "BECMG" or "TEMPO", the entire cloud group, including those cloud layers not expected to change, shall be repeated.

CB layers are the only forecast layers to have cloud type identified, e.g., "BKN040CB".

- k. *Change Groups:* For forecast purposes, all components of the following elements are grouped together:
1. sky condition,
 2. visibility, present weather and obstruction to vision.

Conditions listed after the change group represent new conditions.

In the following example since wind is considered a group on its own, and is not mentioned in the section after the "BECMG" change group, it is unchanged and will remain variable at

CANADA APPENDICES

3 kt. However, changes have occurred to the sky condition and visibility, present weather and obstruction to vision. For the sky condition, the broken layer at 300 ft will no longer exist after 1400Z.

EXAMPLE: TAF CYVP 301213Z 3012/3024 VRB03KT 1/4SM -RA FG BKN003 OVC007
BECMG 3012/3014 4SM -DZ BR OVC007

Plain language explanation of the forecast: TAF for Kuujuaq, Que., issued on the 30th day of the month at 1213Z, valid from the 30th day of the month at 1200Z until the 30th day of the month at 2359Z. Wind variable at 3 kt, visibility 1/4 SM with light rain and fog; forecast cloud layers are broken at 300 ft and overcast at 700 ft. From 1200Z until 1400Z, conditions will become visibility 4 SM with light drizzle and mist; overcast cloud layer at 700 ft.

- l. *Permanent Change Group (Rapid) (FM):* FM is the abbreviation for “from”. It is used for a permanent change to the forecast which will occur rapidly. All forecast conditions given before this group are superseded by the conditions indicated after the group. In other words, a complete forecast will follow and all elements must be indicated, including those for which no change is forecast. The time group represents hours and minutes in UTC.

EXAMPLE: “FM280930” would decode as the beginning of a new part period forecast from the 28th day of the month at 0930Z.

NOTE: Where the permanent change group indicator (FM) indicates a change after the beginning of a whole hour, as in the example above, any subsequent use of a gradual change group (BECMG) or transitory change group (TEMPO) shall indicate changes after the time indicated in hours and minutes in the “from” (FM) indicator. Using the above example, if there was a subsequent use of “TEMPO 2809/2811”, the temporary change would be between 0930Z and 1100Z on the 28th day of the month.

- m. *Permanent Change Group (Gradual) (BECMG):* If a permanent change in a few weather elements is forecast to occur gradually, with conditions evolving over a period of time (normally one to two hours, but not more than four hours), the new conditions that differ from those immediately prior are indicated following “BECMG”. Normally only those elements for which a change is forecast to occur will follow “BECMG.” Any forecast weather element not indicated as part of the “BECMG” group remains the same as in the period prior to the onset of the change.

If a significant change in weather or visibility is forecast, all weather groups, as well as the visibility, are indicated following “BECMG,” including those that are unchanged. When the ending of significant weather is forecast, the abbreviation “NSW” (no significant weather) is used.

The start and stop time of the change period is indicated by two four-digit date/time groups following “BECMG.” The first two digits of each group indicate the date, while the last two digits of each group indicate the time in whole UTC hours.

As a general rule, to keep the forecast clear and unambiguous, the use of the “BECMG” change group is kept to a minimum, and confined to those cases where only one, or at most two, weather groups are expected to change while all the others stay the same. In those

CANADA APPENDICES

cases where more than two groups are expected to change, the permanent change group “FM” will be used to start a new self-contained part period. For the purposes of flight planning, and specifically the selection of IFR alternate airports, if forecast conditions are improving, the new conditions will apply when the change period is complete, and if the conditions are deteriorating, the new conditions will apply at the beginning of the period.

EXAMPLE: “BECMG 2808/2809 OVC030” would decode as a change towards overcast sky conditions at 3000 feet AGL occurring gradually between 0800Z and 0900Z on the 28th day of the month; and

- a. if the previous sky condition forecast was for better than overcast conditions at 3000 feet AGL, then the change would apply as of 0800Z; or
 - b. if the previous sky condition forecast was for worse than overcast conditions at 3000 feet AGL, then the change would apply as of 0900Z.
- n. *Transitory Change Group (TEMPO)*: If a temporary fluctuation in some or all of the weather elements is forecast to occur during a specified period, the new conditions that differ from those immediately prior are indicated following “TEMPO.” In other words, when an element is not indicated after “TEMPO,” it shall be considered to be the same as that for the prior period. The time period, as with “BECMG,” is indicated by the four-digit date/time groups following “TEMPO.” The first two digits of each group indicate the date, while the last two digits of each group indicate the time in whole UTC hours.

EXAMPLE: FM281100 VRB03KT 3SM RA BR OVC020 TEMPO 2812/2815 1SM RA BR FM28150...

In this example, the cloud group “OVC020” is not repeated after “TEMPO” because it is forecast to remain unchanged. On the other hand the weather group “RA BR” is repeated after “TEMPO” because a significant change in visibility is forecast.

When a significant change in weather or visibility is forecast, all weather groups are indicated following “TEMPO,” including those that are unchanged, and any weather element not indicated is forecast to remain the same as in the period prior to the temporary fluctuation. When the ending of significant weather is forecast, the abbreviation “NSW” (no significant weather) is used.

“TEMPO” is only used when the modified forecast condition is expected to last less than one hour in each instance, and if expected to recur, the total period of the modified condition will not cover more than half of the total forecast period. The total period of the modified condition is the time period during which the actual modified weather condition is expected to occur, and not the total time stated for the “TEMPO” time period. When the modified forecast condition is expected to last more than one hour, either “FM” or “BECMG” must be used.

- o. *Probability Group (PROB)*: In order to indicate the probability of occurrence of alternative values of forecast groups, *PROB30* (a 30% probability) or *PROB40* (a 40% probability) is placed directly before the change group’s validity period and alternative value(s) to indicate that different conditions will occur within the specified time period. The time period is given

CANADA APPENDICES

in whole UTC hour values. For example, “PROB30 2817/2821” would indicate that between 1700Z and 2100Z on the 28th day of the month there is a 30% probability that the indicated weather will occur. The weather elements used in the PROB group are restricted to hazards to aviation, which include, but are not limited to, the following:

- thunderstorms;
- freezing precipitation;
- low level windshear at or below 1500 feet AGL; or
- ceiling and visibility values important to aircraft operations (e.g. threshold such as alternate limits, lowest approach limits).

A probability of less than 30% of actual values deviating from those forecasts is not considered to justify the use of the PROB group. When the possibility of an alternative value is 50% or more, this shall be indicated by the use of BECMG, TEMPO or FM, as appropriate.

A PROB can be used with a TEMPO and with a BECMG; however:

1. A PROB must fall entirely within or entirely outside of the hours of a TEMPO and be written after the TEMPO;
 2. A combination of all three (TEMPO, PROB and BECMG) is not permitted; and
 3. A PROB can be followed by a BECMG but must not share any common hours.
- p. *Remarks:* Remarks will appear in TAF from Canada, prefaced by “RMK”. Currently, the following remarks are allowed:
1. *“FCST BASED ON AUTO OBS”* — This remark indicates that the TAF is based on METAR AUTO observations.
 2. *“NXT FCST BY 290000Z”* — This remark indicates the date and time (UTC) the next regular TAF will be issued, which will correspond to the beginning of its new period of validity. This remark will normally mark the end of the TAF.
 3. *PARTIAL PROGRAM NOTICES* — For airports with a partial observing program (e.g. no nighttime observations are taken), a remark is included in the last regular TAF issued for the day to indicate when forecast coverage will resume, e.g., “NXT FCST BY 291045Z”, “NO FCST COVERAGE 2820-2911Z”, or “NO FCST ISSUED UNTIL FURTHER NOTICE”.
 4. *POSSIBLE DISCREPANCIES* — Forecasters will use remarks to explain possible discrepancies between an AWOS and a TAF if the forecasters have reason to believe that the AWOS observations are non-representative of the actual weather at the airport. For example, the remarks could be “RMK AUTO OBS REPG NON-REPRESENTATIVE WND SPD.” or “RMK AUTO OBS REPG NON-REPRESENTATIVE VIS.”

**CANADA
APPENDICES****3.7.4 Aerodrome Forecasts (TAFs) from Automatic Aerodrome Routine Meteorological Reports (METAR AUTO)**

At some sites equipped with AWOS, forecasters will issue an airport forecast (TAF) based in part on the METAR AUTO observations made by AWOS at the airport. The only visible distinction between this forecast and a TAF that is based on human observations is the comment at the end of the TAF “FCST BASED ON AUTO OBS.” The TAF based on automated observations, like the TAF based on human observations, provides a description of the most probable weather conditions expected to occur at an airport together with the most probable time of occurrence.

The abbreviated comment “FCST BASED ON AUTO OBS” at the end of the TAF is meant to inform pilots that the forecast has been developed from an automated weather observation. The pilot using this forecast should be familiar with the characteristics of METAR AUTO weather observations and the comparison of automated and human observations contained in paragraph 3.8.5; e.g., AWOS cloud height sensor tends to under-read during precipitation events. The forecaster is also familiar with AWOS characteristics and has taken time to analyze not only AWOS data, but also additional information such as satellite and radar imagery, lightning data, remote video imagery, pilot reports and observations from surrounding stations. Based on integration of this data, the forecaster may have inferred actual weather conditions that differ slightly from the METAR AUTO report. On those few occasions when there are differences between a METAR AUTO report and a TAF, it may not imply that the TAF is inaccurate, or that an amendment is required. In the event that an AWOS sensor is missing, inoperative or functioning below standards, the forecaster will attempt to infer the value of the missing weather element from other available data. If the forecaster is unable to infer the weather conditions, a decision may be made to cancel the TAF, pending correction of the problem. The decision to cancel will depend on the weather conditions prevailing at the time, and how critical the missing information is to the issuance of a credible TAF based on the automated data that is available.

3.7.5 Amended Aerodrome Forecast (TAF)

An aerodrome forecast (TAF) is amended when the forecast conditions are no longer representative of the actual or expected conditions. An amendment is issued in response to a METAR, SPECI or a PIREP indicating a significant change in weather relative to the conditions forecast in the TAF or whenever, in the forecaster’s judgment, the TAF is not representative of existing or expected weather conditions.

The amendment criteria include thresholds defined by changes in ceiling, visibility, present weather, wind speed and direction or the existence of low level wind shear. TAF amendments are issued for weather that is better than previously forecasted as well as for weather that is worse than previously forecasted.

An amendment will also be issued to correct a TAF when typographical errors and/or forecast text omissions are such that the information content of the TAF is unclear.

An amended forecast covers the remaining period of the original forecast and is identified by “TAF AMD” in place of “TAF” prior to the airport identifier in the first line of the forecast. In all cases, the issue time added to the body of the TAF will always indicate which TAF is the latest.

CANADA APPENDICES

A TAF does not have to be amended for changes in ceiling and/or visibility when both the forecast and observed values are below the normal VFR minima or the lowest published instrument landing minima for an airport (whichever is lower).

The VFR minima criteria for TAF amendment purposes are a ceiling of less than 1000 ft and/or ground visibility of less than 3 SM.

3.8 AERODROME ROUTINE METEOROLOGICAL REPORTS (METARs)

3.8.1 The METAR Code

An aviation weather report describes the actual weather conditions at a specified location and at a specified time as observed from the ground. METAR is the name of the international meteorological code for an aviation *routine* weather report. METAR observations are normally taken and disseminated on the hour. A SPECI, the name of the code for an aviation selected *special* weather report, will be reported when weather changes of significance to aviation are observed (see paragraph 3.8.4).

In Canada, METAR and SPECI reports are not encoded by the observer, but are generated by computer software, based on hourly or special observations taken at either staffed or automatic sites.

The code is composed of several groups which are always in the same relative position to one another. When a weather element or phenomenon does not occur, the corresponding group (or extension) is omitted. Certain groups may be repeated.

METARs and SPECIs will be disseminated in ICAO meteorological information exchange model (IWXXM) geography markup language (GML) form. The technical specifications for IWXXM are contained in the *Manual on Codes* (WMO [World Meteorological Organization]-No. 306), Volume I.3, Part D. Guidance on the implementation of IWXXM is provided in the *Manual on the ICAO Meteorological Information Exchange Model* (Doc 10003).

The large majority of METARs and SPECIs are provided by NAV CANADA; however, at DND airports they are provided by DND. If METARs and SPECIs are being provided by another source, they will be indicated as being “private” in the CFS. For these sites, the airport operator is the primary contact for further information.

3.8.2 National Variations

Despite the fact that METAR is an international code, there are some national variations. For example, wind speed may be reported in different units; however, the units are always appended to the values to avoid any misunderstanding. See Meteorology – General Information paragraph 1.1.8 for more information on differences from ICAO Annex 3.

3.8.3 Sample Message

METAR CYXE 292000Z CCA 09015G25KT 3/4SM R09/4000FT/D –RA BR BKN008 0VC040
21/19 A2992 WS RWY 09 RMK SF5NS3 VIS NW 3/8 SLP134 DENSITY ALTITUDE 2500FT

CANADA
APPENDICES

- a. **Decoding of Example** — Aviation routine meteorological report; Saskatoon, Saskatchewan, issued on the 29th day of the month at 2000 UTC; first correction to the original observation; wind 090° true, 15 kt with gusts to 25 kt; visibility 3/4 SM; RVR for Runway 09 is 4000 ft and has had a downward tendency; present weather is light rain and mist; broken clouds at 800 ft AGL, and combined with the lower layer, overcast clouds at 4000 ft; temperature 21°C; dew point 19°C; altimeter setting 29.92 in Hg; wind shear Runway 09; remarks: stratus fractus 5/8, nimbostratus 3/8, visibility to the northwest 3/8 SM, sea level pressure 1013.4 hPa, density altitude 2500 ft.
- b. **Report Type** — The code name METAR (or SPECI) is given in the first line of text. A SPECI is issued only when significant changes in weather conditions occur *off the hour*.
- c. **Location Indicator** — Canadian aviation weather reporting stations are assigned four-letter ICAO indicators commencing with C and followed by either W, Y, or Z. These stations are normally located within 1.6 NM (3km) of the geometric center of the runway complex.
- d. **Date/Time of Observation** — The date (day of the month) and time (UTC) of the observation is included in all reports. The official time of the observation (*on the hour*) is used for all METAR reports that do not deviate from the official time by more than 10 minutes. In SPECIs, the time refers to the time of occurrence (hours and minutes) of the change(s) which required the issue of the report.
- e. **Report Modifier** — This field may contain two possible codes; they are “AUTO” or “CCA”. Both codes may also appear simultaneously, i.e., “AUTOCCA”. “AUTO” will be used when data for the primary report is gathered by an AWOS. See paragraph 3.8.5 for more information about AWOS reports. “CCA” is used to indicate corrected reports; the first correction as CCA, the second as CCB, etc.
- f. **Wind** — This group reports the 2-minute mean wind direction and speed, along with gusts. Wind *direction* is always *three digits*, given in degrees (true) but rounded off to the nearest 10 degrees (the third digit is always a “0”). Wind *speeds* are *two digits* (or three digits if required), in knots. Calm is encoded as “00000KT”. In Canada the unit for wind speed is knots (nautical miles per hour) and is indicated by including “KT” at the end of the wind group. Other countries may use kilometers per hour (KMH), or meters per second (MPS).
1. **Wind Gusts** — Gust information will be included if gust speeds, averaged over a 5-second period, exceed the average wind speed by 5 knots or more in the 10-minute period preceding the observation and the peak gust reaches a maximum speed of 15 knots or more. “G” indicates gusts and the peak gust is reported, using two or three digits as required.
 2. **Variations in Wind Direction** — This group reports variations in wind direction. It is only included if, during the 10-minute period preceding the observation, the direction varies by 60 degrees or more and the mean speed exceeds 3 knots. The two extreme directions are encoded in clockwise order. In the example below, the wind is varying from 260 degrees (true) to 340 degrees (true).

EXAMPLE: METAR CYWG 172000Z 30015G25KT 260V340

CANADA
APPENDICES

In the case of variable wind direction, wind direction in tens of degrees (ddd) shall be coded as VRB when the wind speed is less than 3 kt. A variable wind at higher speeds shall be reported only when the variation in wind direction is 180° or more or when it is impossible to determine a single wind direction.

EXAMPLE: METAR CYQB 041500Z VRB02KT

3. When wind sensors are not functioning at a human METAR site, the wind speed and direction will be estimated and a remark will be added to the report ("WND ESTD").
- g. **Prevailing Visibility** — The prevailing visibility is reported in statute miles and fractions. There is no maximum visibility value reported. Lower sector visibilities which are half or less of the prevailing visibility are reported as remarks at the end of the report.
- h. **Runway Visual Range** — The runway visual range (RVR) for the touchdown zone of up to four available landing runways is reported as a *10-minute average*, based on the operational runway light settings at the time of the report. It is included if the prevailing visibility is 1 statute mile or less, and/or the runway visual range is 6000 feet or less. "R", the group indicator, is followed by the runway designator (e.g., "06"), to which may be appended the letters "L", "C", or "R" (left, center, or right) if there are two or more parallel runways. The value of runway visual range is then reported in hundreds of feet, using three or four digits. FT indicates the units for runway visual range are feet. "M" preceding the lowest *measurable* value (or "P" preceding the highest) indicates the value is *beyond* the instrument range. The runway visual range trend is then indicated if there is a distinct upward or downward trend from the first to the second 5-minute part-period such that the runway visual range changes by 300 feet or more (encoded "U" or "D" for upward or downward) or if no distinct change is observed, the trend "N" is encoded. If it is not possible to determine the trend the field will be left blank.
- i. **Variations in RVR** — Two RVR values may be reported, the *minimum* and *maximum* one-minute mean RVR values during the 10-minute period preceding the observation, if they vary from the 10-minute mean by at least 20% (and by 150 feet).

EXAMPLE: "R06L/1000V2400FT/U" decodes as: the minimum RVR for Runway 06 Left is 1000 feet; the maximum RVR is 2400 feet; and the trend is upward.
- j. **Present Weather** — The present weather is coded in accordance with the World Meteorological Organization (WMO) Code, Table 4678 which follows. As many groups as necessary are included, with each group containing from 2 to 9 characters.

Present weather is comprised of *weather phenomena*, which may be one or more forms of *precipitation*, *obscuration*, or *other phenomena*. Weather phenomena are preceded by one or two *qualifiers*; one of which describes either the intensity or proximity to the station of the phenomena, the other of which describes the phenomena in some other manner.

**CANADA
APPENDICES**

**WMO Code, Table 4678
(incorporating Canadian differences)
SIGNIFICANT PRESENT WEATHER CODES**

QUALIFIER		WEATHER PHENOMENA						
Intensity or Proximity	Descriptor		Precipitation		Obscuration		Other	
1	2		3		4		5	
<i>NOTE: Pre- cipitation in- tensity refers to all forms combined.</i>	MI	Shallow	DZ	Drizzle	BR	Mist (Vis $\geq$ 5/8 SM)	PO	Dust/Sand Whirls (Dust Devils)
	BC	Patches	RA	Rain				
	PR	Partial	SN	Snow	FG	Fog (Vis < 5/8 SM)	SQ	Squalls
	DR	Drifting	SG	Snow Grains				
- Light	BL	Blowing	IC	Ice Crystals (Vis $\leq$ 6 SM)	DU	Dust (Vis $\leq$ 6 SM)	FC	Funnel Cloud
	SH	Shower(s)						
Moderate (no qualifier)	TS	Thunderstorms	PL	Ice Pellets	SA	Sand (Vis $\leq$ 6 SM)	SS	Sandstorm (Vis < 5/8 SM) (+SS Vis < 5/16 SM)
			GR	Hail				
+ Heavy	FZ	Freezing	GS	Snow Pellets	HZ	Haze (Vis $\leq$ 6 SM)	DS	Duststorm (Vis < 5/8 SM) (+DS Vis < 5/16 SM)
VC In the vi- cinity			UP	Unknown Precipitation (AWOS only)	VA	Volcanic Ash (with any visibili- ty)		

k. Qualifiers

1. *Intensity:* (–) Light (no sign) Moderate (+) Heavy

CANADA APPENDICES

If the intensity of the phenomena being reported in a group is either light or heavy, this is indicated by the appropriate sign. No sign is included if the intensity is moderate, or when an intensity is not relevant.

If more than one type of precipitation is reported together in a group, the predominant type is given first; however, the reported intensity represents the “overall” intensity of the combined types of precipitation.

2. *Proximity*: The proximity, qualifier “VC”, is used in conjunction with the following phenomena:
- SH (showers);
 - FG (fog);
 - FC (funnel cloud)
 - +FC (tornado or waterspout)
 - TS (thunderstorm)
 - BLSN, BLDU, BLSA (blowing snow, blowing dust, blowing sand);
 - PO (dust/sand whirls);
 - DS (duststorm); and
 - SS (sandstorm).

“VC” is used if these phenomena are observed within 5 SM, but not at the station. When VC is associated with “SH”, the type and intensity of precipitation is not specified because it cannot be determined.

3. *Descriptor*: No present weather group has more than one descriptor. The descriptor MI (shallow), BC (patches) and PR (partial) are used only in combination with the abbreviation FG (fog), e.g., “MIFG”.

The descriptors DR (drifting) and BL (blowing) are used only in combination with SN (snow), DU (dust) and SA (sand). Drifting is used if the snow, dust or sand is raised less than two meters above ground; if two meters or more, blowing is used. If blowing snow (BLSN) and snow (SN) are occurring together, both are reported but in separate present weather groups, e.g., “SN BLSN”.

SH (shower) is used only in combination with precipitation types RA (rain), SN (snow), PL (ice pellets), GR (hail), and GS (snow pellets) if occurring at the time of observation, e.g., “SHPL” or “-SHRAGR”. SHGS refers to either snow pellet showers or small hail (less than 5mm diameter). When it is used for small hail, the diameter of the hail is included in remarks and CB are usually present.

TS (thunderstorm) is either reported alone or in combination with one or more of the precipitation types. The end of a thunderstorm is the time at which the last thunder was heard, followed by a 15-minute period with no further thunder.

CANADA APPENDICES

TS and SH are not used together, since present weather groups can have only one descriptor.

FZ (freezing) is used only in combination with the weather types DZ (drizzle), RA (rain), and FG (fog).

- i. **Weather Phenomena** — Different forms of precipitation are combined in one group, the predominant form being reported first. The intensity qualifier selected represents the overall intensity of the entire group, not just one component of the group. The one exception is freezing precipitation (FZRA or FZDZ), which is always reported in a separate present weather group. Obstructions to vision are generally reported if the prevailing visibility is 6 SM or less, with some exceptions. Any obscuration occurring simultaneously with one or more forms of precipitation is reported in a separate present weather group. Other phenomena are also reported in separate groups, and, when funnel clouds, tornados or waterspouts are observed, they will be coded in the present weather section, as well as being written out in their entirety in remarks.

- I. **Sky Conditions** — This group reports the sky condition for layers aloft. A vertical visibility (VV) is reported in hundreds of feet when the sky is obscured. All cloud layers are reported based on the summation of the layer amounts as observed from the surface up, reported as a height above the station elevation in increments of 100 feet to a height of 10,000', and thereafter in increments of 1000'. The layer amounts are reported in eighths (oktas) of sky coverage as follows:

SKC	"sky clear"	no cloud present
FEW	"few"	>0 to 2/8 summation amount
SCT	"scattered"	3/8 to 4/8 summation amount
BKN	"broken"	5/8 to 8/8 summation amount
OVC	"overcast"	8/8 summation amount
CLR	"clear"	clear below 25,000 feet as interpreted by an AWOS

Significant convective clouds (cumulonimbus or towering cumulus only), if observed, are identified by the abbreviations CB (Cumulonimbus) or TCU (Towering Cumulus), which are appended to the cloud group without a space, e.g., "SCT025TCU".

When observed, CB and TCU of any amount are always reported in the remarks of the airport routine meteorological report (METAR) or airport special meteorological report (SPECI), even if they are only embedded or distant.

When either CB or TCU is the predominant cloud type in a layer reported in the cloud group of the METAR/SPECI, the applicable cloud type (CB or TCU) is included within the cloud group. When an individual layer of cloud is composed of CB *and* TCU with a common cloud base, the type shall be reported as CB only.

CANADA APPENDICES

The automated weather observation system (AWOS) cannot report cloud types. AWOS cloud layers are limited to four, and will report clear (CLR) when no layers are detected below a base of 25,000 ft (some private AWOS are limited to cloud bases 10,000 ft).

A ceiling is the lesser of the following: the height above ground or water of the base of the lowest layer of cloud covering more than half of the sky, **or** the vertical visibility in a surface-based layer which completely obscures the whole sky. Therefore, a ceiling exists at the height of the first layer for which a coverage symbol of BKN or OVC is reported. The existence of a vertical visibility constitutes an obscured ceiling.

- m. **Temperature and Dew Point** — This group reports the air temperature and the dew point temperature, rounded to the nearest whole Celsius degree (e.g., +2.5°C would be rounded to +3°C). Negative values are preceded by the letter M, and values with a tenths digit equal to precisely 5 are rounded to the warmer whole degree. For example, 2.5, -0.5, -1.5, and -12.5 would be reported as 03, M00, M01 and M12, respectively.
- n. **Altimeter Setting** — This group reports the altimeter setting. A is the group indicator followed by the altimeter setting indicated by a group of four figures representing tens units, tenths, and hundredths of inches of mercury. To decode, place a decimal point after the second digit (e.g., A3006 becomes 30.06).
- o. **Wind shear** — This group contains reports of low level wind shear (within 1500' AGL) along the takeoff or approach path of the designated runway. The two number runway identifier is used, to which the letters "L", "C", or "R" may be appended. If the existence of wind shear applies to all runways, "WS ALL RWY" is used.
- p. **Remarks** — Remarks will appear in reports from Canada, prefaced by RMK. Remarks will include, where observed, layer type and cloud or obscuring phenomena (in eighths of sky covered or oktas), general weather remarks, and sea level pressure, as required. The sea level pressure, prefixed by "SLP" and indicated in hectopascals, will be the last mandatory field in the METAR. SLP does not directly relate to altimeter setting as the SLP is based upon actual temperatures while the altimeter setting is based upon the ICAO standard atmosphere. Density altitude will be indicated after sea level pressure when the density altitude is 200 ft or more than the aerodrome elevation. The remarks "PRESFR" and "PRESRR" indicate rapid changes in pressure and pilots should be extra vigilant to ensure that they have the most recent altimeter setting when these remarks are included. The equal sign ("=") is often used as an end-of-message indicator and has no other meaning.

Abbreviations for cloud types

CI	=	cirrus
CS	=	cirrostratus
CC	=	cirrocumulus
AS	=	altostratus
AC	=	altocumulus

**CANADA
APPENDICES****Abbreviations for cloud types**

NS	=	nimbostratus
ST	=	stratus
SF	=	stratus fractus
SC	=	stratocumulus
ACC	=	altocumulus castellanus
CU	=	cumulus
CF	=	cumulus fractus
TCU	=	towering cumulus
CB	=	cumulonimbus

3.8.4 Aerodrome Special Meteorological Reports (SPECI)**3.8.4.1 *Criteria for Taking Special Weather Reports***

Special observations will be taken promptly, to report changes which occur between scheduled transmission times, whenever one or more of the following elements has changed in the amount specified. The amount of change is with reference to the preceding routine or special observation.

- a. ***Ceiling*** — The ceiling decreases to less than, or increases to equal or exceed the following values of height:
1. 1500 ft
 2. 1000 ft
 3. 500 ft
 4. *400 ft
 5. 300 ft
 6. *200 ft
 7. *100 ft
 8. the lowest published minimum

Criteria marked with an asterisk (*) are applicable only at airports with precision approaches, and only down to and including the lowest published minima for these airports.

- b. ***Sky Condition*** — A layer aloft is observed below 1000' and no layer aloft was reported below this height in the report immediately previous, or below the highest minimum for IFR straight-in landing or takeoff, and no layer was reported below this height in the report immediately previous.
- c. ***Visibility*** — Prevailing visibility decreased to less than, or increases to equal to or greater than:

CANADA
APPENDICES

1. 3 SM
2. 1 1/2 SM
3. 1 SM
4. 3/4 SM*
5. 1/2 SM
6. 1/4 SM*
7. the lowest published minimum

Criteria marked with an asterisk (*) are applicable only at airports with precision approaches, and only down to and including the lowest published minima for these airports.

- d. ***Tornado, Waterspout, or Funnel Cloud*** — If one or more of these phenomena:
1. is observed,
 2. disappears from sight, or
 3. is reported by the public (from reliable sources) to have occurred within the preceding six hours and not previously reported by another station.
- e. ***Thunderstorm*** — When storm activity:
1. begins,
 2. intensity increases to become “heavy” thunderstorm, or
 3. ends (SPECI shall be made when 15 minutes have elapsed without the occurrence of thunderstorm activity).
- f. ***Precipitation*** — When any of the following begins, ends or changes intensity:
1. freezing rain
 2. freezing drizzle
 3. ice pellets (showery and non-showery)
 4. rain
 5. rain showers
 6. drizzle
 7. snow
 8. snow showers
 9. snow grains
 10. hail
 11. snow pellets
 12. ice crystals begin or end

**CANADA
APPENDICES**

SPECIs shall be taken as required to report the beginning and ending of each individual type of precipitation, regardless of simultaneous occurrences of other types. A leeway of up to 15 minutes is allowed after the ending of precipitation before a SPECI is mandatory.

EXAMPLE: –RA to –SHRA; SPECI not required.

- g. **Obstruction to vision** — SPECI shall be taken to report the beginning or end of freezing fog.
- h. **Wind** — A SPECI shall be taken to report when the wind:
1. speed (two minute mean) increases suddenly to at least double the previously reported value and exceeds 30 kt;
 2. direction changes sufficiently to fulfill criteria required for a “wind shift”.
- i. **Temperature** — A SPECI shall be taken to report when the temperature
1. increases by 5°C or more from the previous reported value and the previous reported value was 20°C or higher; or
 2. decreases to a reported value of 2°C or lower.

The following airports have been identified for SPECI criteria for significant temperature changes between hourly reports:

1. Calgary Intl, Alta.
2. Edmonton Intl, Alta.
3. Gander Intl, N.L.
4. Moncton/Greater Moncton Intl, N.B.
5. Montréal/Pierre Elliott Trudeau Intl, Que.
6. Montréal/Mirabel Intl, Que.
7. Ottawa/Macdonald-Cartier Intl, Ont.
8. St. John's Intl, N.L.
9. Toronto/Lester B. Pearson Intl, Ont.
10. Vancouver Intl, B.C.
11. Victoria Intl, B.C.
12. Halifax Intl, N.S.
13. London, Ont.
14. Québec/Jean Lesage Intl, Que.
15. Whitehorse Intl, Y.T.
16. Winnipeg Intl, Man.
17. Yellowknife, N.W.T.

**CANADA
APPENDICES**

18. Charlottetown, P.E.I.
19. Fredericton, N.B.
20. Prince George, B.C.
21. Regina Intl, Sask.
22. Saint John, N.B.
23. Saskatoon/John G. Diefenbaker Intl, Sask.
24. Thunder Bay, Ont.

j. **Volcanic eruption** — A SPECI shall be issued when a volcano erupts.

3.8.4.2 Local Criteria

Additional criteria may be established to meet local requirements.

3.8.4.2.1 OBSERVER'S INITIATIVE

The criteria specified in the preceding paragraphs shall be regarded as the minimum requirements for taking special observations. In addition, any weather condition that, in the opinion of the observer is important for the safety and efficiency of aircraft operations or otherwise significant, shall be reported by a special observation.

3.8.4.2.2 CHECK OBSERVATIONS

Check observations are taken between regular hourly observations to ensure that significant changes in weather do not remain unreported. If such an observation does not reveal a significant change, it is designated as a "check observation". If a significant change has occurred, the report is treated as a "special observation".

A check observation shall be taken whenever a PIREP is received from an aircraft within 1 1/2 SM of the boundary of an airfield, and the PIREP indicates that weather conditions, as observed by the pilot, differ significantly from those reported by the current observation (i.e., the PIREP indicated that a special report may be required). This check observation should result in one of the following:

- a. transmission of a special observation over regular communications channels; or
- b. if no special observation is warranted, transmission of the check observation, together with the PIREP, to local airport agencies.

3.8.5 Automatic Aerodrome Routine Meteorological Reports (METAR AUTO) and Limited Weather Information System (LWIS) Reports**3.8.5.1 Automatic Aerodrome Routine Meteorological Reports (METAR AUTO)**

Automated aviation weather observations are an integral component of the aviation weather reporting system in Canada and there are currently more than 80 in operation in all regions of the country. They were developed to provide an alternative method of collecting and disseminating weather observations from sites where human observation programs could not be supported.

CANADA APPENDICES

AWOS provides accurate and reliable data, but does have limitations and characteristics that are important to understand when using the information.

NAV CANADA AWOS that produces METAR AUTO reports incorporates sensors capable of measuring cloud base height (up to 25,000 ft AGL); sky cover; visibility; temperature; dew point; wind velocity; altimeter setting; precipitation occurrence, type, amount, and intensity; and the occurrence of icing.

METARs and SPECIs based on automated weather observations include the word “AUTO”. METAR AUTO observations are reported on the hour and SPECI AUTO observations are issued to report significant changes in cloud ceiling, visibility and wind velocity, as well as the onset and cessation of thunderstorms, precipitation or icing. AWOS operated by NAV CANADA and DND issue METAR AUTO reports and, when appropriate, SPECI AUTO reports.

AWOS is based on sensors that sample the atmosphere and prepare a data message every minute. If the observed weather conditions have changed significantly enough to meet the SPECI criteria, and subject to the various processing algorithms, a SPECI AUTO will be issued. Human observers view the entire celestial dome and horizon; this results in a naturally smoothed and more representative value for ceiling and visibility. Because of the precise measurement, continuous sampling and unidirectional views of the sensors, NAV CANADA AWOS will produce more SPECI AUTO observations than human observation sites (5 to 6 percent of the time AWOS SPECI counts exceed six per hour). In cases where there are several AWOS reports issued over a short period of time, it is important to summarize the observations to gain an appreciation of the weather trend. One report in a series should not be expected to represent the prevailing condition.

3.8.5.2 *LWIS Reports*

LWIS is an automated weather system which produces an hourly report containing wind speed and direction; temperature; dew point; and altimeter setting. LWIS is designed for use at airports where provision of METAR and SPECI AUTO is not justified, but support for a CAP approach is required.

EXAMPLE: LWIS CYXP 221700Z AUTO 25010G15KT 03/M02 A3017=

3.8.5.3 *AWOS and LWIS Performance Characteristics*

All AWOS and LWIS operated by NAV CANADA have the following performance characteristics.

- a. Thunderstorm reporting (AWOS) at sites within the domain of the Canadian Lightning Detection Network (CLDN). Thunderstorm activity, based on the proximity of the lightning strike(s) to the site, will be reported as:
 - (i) TS — Thunderstorm (at site), if lightning detected at 6 SM or less;
 - (ii) VCTS — Thunderstorm in vicinity, if lightning detected from > 6 to 10 SM;
 - (iii) LTNG DIST (direction) — If lightning detected from > 10 to 30 SM, lightning distant with octant compass cardinal direction shall be reported in remarks, e.g. LTNG DIST NE, S, SW; and
 - (iv) LTNG DIST ALL QUADS — Lightning distant all quadrants will be reported in remarks if lightning is detected in four or more octants.

**CANADA
APPENDICES**

- b. Ice-resistant anemometer (AWOS and LWIS) — New ice-resistant technology essentially eliminates anemometer performance degradation due to freezing precipitation, freezing fog or snow contamination.
- c. Freezing drizzle and drizzle are not reported. When drizzle is occurring the AWOS will usually report either rain or unknown precipitation. When freezing drizzle is occurring the AWOS will usually report either freezing rain or freezing precipitation of an unknown type.
- d. Density altitude reporting capability (AWOS and LWIS) — Density altitude is the altitude in International Standard Atmosphere (ISA) at which the air density would be equal to the air density at field elevation at the current temperature. This remark is only added when the density altitude, rounded to the nearest 100 ft, is 200 ft or higher than the airport elevation. A rough value of density altitude can be approximated by adding 118.8 ft to the airport pressure altitude for every degree Celsius the temperature is above ISA. Density altitude can also be less than airport elevation and can be estimated by subtracting 118.8 ft from the airport pressure altitude for every degree Celsius colder than ISA, but it is not reported.
- e. Visibility (AWOS) — Visibility will be reported in daytime and at night in a manner similar to human assessment.
- f. Ceilometer — AWOS is capable of reporting cloud bases up to 25,000 ft.
- g. “Obstructions to vision” reporting capability — (AWOS) is able to report haze (HZ); mist (BR); fog (FG); freezing fog (FZFG); and blowing snow (BLSN).
- h. Voice generator sub-system (VGSS) — Text-to-voice technology at many sites for local VHF transmission of weather report to pilots.
- i. Icing — The occurrence of icing at the time of observation or during the past hour will be noted in remarks.
- j. RVR reporting (AWOS) at sites where RVR sensors are installed.
- k. Digital aviation weather cameras (WxCam) are installed at stand-alone locations as well as at many AWOS and LWIS sites.

All regulated observations of wind speed, direction and character, temperature, dew point and altimeter setting must meet the same performance specifications regardless of the means of assessment (either human or automated). Among these requirements is that all reports of altimeter setting must be based upon a fail-safe design that utilizes two or more pressure sensors that must agree within established tolerances before they can be included in a report.

3.8.5.4 *METAR AUTO Reports and Human Observation Comparison*

METAR AUTO provided by NAV CANADA AWOS and METAR issued by human are compared in the following table.

CANADA APPENDICES

OBSERVATION COMPARISON TABLE

WX Report Parameter	Human Observation	NAV CANADA METAR AUTO
Report Type	METAR or SPECI	METAR or SPECI
Location Indicator	Four-letter indicator (e.g., CYQM, CYVR).	No difference.
	At stations where the observer is not on the airport, (beyond 1.6 NM (3km) of the geometric center of the runway complex) the Wx report indicator differs from the airport indicator, e.g., Cartwright airport is CYCA; the Wx report is identified as CWCA.	No difference.
Report Time	Date and time in UTC, followed by a "Z", e.g. 091200Z.	No difference.
Type Indicator		AUTO
Corrections Indicator	Corrections can be issued, e.g., "CCA". The "A" indicates the first correction.	Not applicable.
Wind	A two-minute average direction in degrees true; speed in kt; "G" represents a gust, e.g., 12015G25KT.	No difference.
	Human observers shall provide an estimate of wind speed and direction in the event of wind sensor failure.	No difference. <i>NOTE: When a VGSS is installed, the wind direction will be broadcast in degrees magnetic if the AWOS is located in Southern Domestic Airspace; elsewhere, it will be broadcast in degrees true. If wind information is missing, five forward slashes (/) are placed in the wind field, e.g. /////.</i>
Variable Wind Group	Wind direction variation of 60° or greater.	No difference.
Visibility	Reported in SM up to 15 mi. After 15 mi., it is reported as 15+; e.g., 10 SM.	Reported in SM up to 9 mi.

**CANADA
APPENDICES**

OBSERVATION COMPARISON TABLE

WX Report Parameter	Human Observation	NAV CANADA METAR AUTO
	Fractional visibilities are reported.	No difference.
	Visibility is prevailing visibility, i.e., common to at least half the horizon circle.	Visibility is measured using fixed, unidirectional, forward scatter techniques.
		Reported visibilities tend to be comparable to (especially with visibility less than 1 SM) or higher than human observations in precipitation.
		Reported visibilities at night are the same as the day and tend to be comparable to or higher than human observations.
RVR	Runway direction, followed by the visual range in feet, followed by a trend. RVR will be reported where equipment is available.	No difference.
Weather Group	See the table following paragraph 3.8.3 j. for the symbols used for obstructions to visibility (e.g., smoke, haze).	AWOS are capable of reporting FG, FZFG, BR, BLSN and HZ.
	See the table following paragraph 3.8.3 j. for the symbols used for the description of weather.	AWOS will report weather phenomena by the following symbols: RA – rain, FZRA – freezing rain, SN – snow, UP – unknown precipitation type. New AWOS is capable of reporting TS and including remarks on location of lightning. Drizzle (DZ) or freezing drizzle (FZDZ) are not reported and will usually be reported as rain (RA or FZRA) or unknown precipitation type (UP or FZUP).

**CANADA
APPENDICES**

OBSERVATION COMPARISON TABLE

WX Report Parameter	Human Observation	NAV CANADA METAR AUTO
	"+" or "-" is used to indicate weather intensity.	No difference. Squalls are not reported. AWOS does not report "in the vicinity" phenomena other than TS and lightning. AWOS may sporadically report freezing precipitation at temperatures above 0°C and below +3°C, during periods of wet snow, rain, drizzle or fog.
Cloud Amount and Sky Conditions	Observer views entire celestial dome and determines cloud-base height, layer amounts and opacity, and cumulative amount and opacity.	Laser ceilometer views one point directly over the station. It measures the cloud-base height, then uses time integration to determine layer amounts.
	SKC or height of cloud base plus FEW, SCT, BKN, OVC.	Height of cloud base plus FEW, SCT, BKN, OVC. "CLR" is reported if no cloud below 25,000 ft AGL is detected.
	Surface-based layers are prefaced by "VV" and a three-figure vertical visibility.	No difference.
	The cloud layer amounts are cumulative.	No difference.
		Multiple overcast layers can be detected and reported.
		Ceilometer may occasionally detect ice crystals, smoke aloft or strong temperature inversion aloft and report them as cloud layers.
		Reported cloud layers in precipitation are comparable to or lower than human observations.
Temperature and Dewpoint	Temperature then dew point expressed as a two-digit number in degrees Celsius, separated by a forward slash (/) and preceded by an "M" for below freezing temperatures; e.g., 03/M05.	Check GFA and TAF for further information.
		No difference.

CANADA APPENDICES

OBSERVATION COMPARISON TABLE

WX Report Parameter	Human Observation	NAV CANADA METAR AUTO
Altimeter Setting	An "A" followed by a four-digit number in inches of mercury, e.g., A2997.	No difference.
Wind Shear	Existence in the lower layers shall be reported.	Not reported.
Supplementary Information (Remarks)	See the table in paragraph 3.8.3 j. for the symbols used to describe clouds and obscuring phenomena.	Clouds and obscuring phenomena are not described in METAR AUTO or SPECI AUTO reports.
	Significant weather or variation not reported elsewhere in the report.	Currently, remarks are limited. When the visibility is variable, the remark VIS VRB followed by the limits will appear, e.g., VIS VRB 1–2. When icing is detected, ICE, ICE INTMT, or ICE PAST HR will appear. Remarks on precipitation amount, rapid changes in pressure and the location of lightning may also appear.
Barometric Pressure	The last remark in the METAR or SPECI is the mean sea level pressure in hectopascals, e.g., SLP127 (1012.7 hPa).	No difference.
Density altitude	Density altitude for heights 200 ft above airport elevation. The dry air density altitude will be included in the remarks.	No difference.

Example of METAR issued by human observation:

EXAMPLE: METAR CYEG 151200Z CCA 12012G23KT 3/4SM R06R/4000FT/D -RA BR FEW008 SCT014 BKN022 OVC035 10/09 A2984 RMK SF1SC2SC4SC1 VIS W2 SLP012=

Example of METAR AUTO issued by NAV CANADA's AWOS system:

EXAMPLE: METAR CZVL 151200Z AUTO 12012G23KT 3/4SM -RA FEW008 SCT014 BKN022 OVC035 10/09 A2984 RMK SLP012=

NOTE: If an AWOS sensor is malfunctioning or has shut down, that parameter will be missing from the report.

**CANADA
APPENDICES****3.8.6 Voice Generation Systems**

Where a voice generator sub-system (VGSS), very high frequency (VHF) radio and/or telephone are connected to the AWOS or LWIS, the most recent data gathered once each minute will be broadcast to pilots on the VHF frequency and/or via the telephone number published in the *Canada Flight Supplement* (CFS). A pilot with a VHF receiver should be able to receive the VGSS transmission at a range of 75 NM from the site at an altitude of 10,000 ft AGL. Weather data will be broadcast in the same sequence as that used for METARs and SPECIs.

A human-observed METAR/SPECI or a METAR AUTO/SPECI AUTO shall take priority over an automated voice generated report (minutely reports). During the hours when a human observation program is operating and there is no direct VHF communication between the pilot and weather observer, the VGSS VHF transmitter will normally be off. This eliminates the risk of a pilot possibly receiving two contradictory and confusing weather reports.

In variable weather conditions, there may be significant differences between broadcasts only a few minutes apart. It is very important during these conditions to obtain several broadcasts of the minutely data for comparison to develop an accurate picture of the actual conditions to be expected at the location.

Below is the typical format of a NAV CANADA AWOS message:

“(site name) AUTOMATED WEATHER OBSERVATION SYSTEM — OBSERVATION TAKEN AT (time) — WIND (direction) (MAGNETIC/TRUE) AT (speed) KNOTS — VISIBILITY (visibility data) — (present weather data) — (sky condition/cloud data) — TEMPERATURE (temperature data) — DEW POINT (dew point data) — ALTIMETER (altimeter data)”

Below is an example of the LWIS message:

“(site name) LIMITED WEATHER INFORMATION SYSTEM — CURRENT OBSERVATION TAKEN AT (time) — WIND (direction) (MAGNETIC/TRUE) (speed) KNOTS — TEMPERATURE (temperature data) — DEW POINT (dew point data) — ALTIMETER (altimeter data)”

NOTE: Missing data or data that has been suppressed is transmitted as “MISSING”.

CANADA APPENDICES

3.9 UPPER LEVEL WINDS AND TEMPERATURES

3.9.1 Canadian Forecast Winds and Temperatures Aloft Network

3.9.2 Upper Level Wind and Temperature Forecasts (FD)

Upper level wind and temperature forecasts (FD) are upper level forecasts of wind velocity, expressed in knots (kt), to the nearest 10°T and temperature, expressed in degrees Celsius (°C). Temperatures are not forecast for 3000 feet; in addition, this level is omitted if the terrain elevation is greater than 1500 feet. All forecast temperatures for altitudes over 24,000 ft are negative.

CANADA APPENDICES

Data for the production of FD forecasts are derived from a variety of atmospheric data sources, including upper air sounding measurements of pressure, temperature, relative humidity and wind velocity, taken at 32 sites twice daily (at 0000Z and 1200Z). Following the computer run of a subsequent numeric weather model, FD forecasts are available at the times issued or periods of coverage indicated in paragraph 3.1.

EXAMPLE 1:

EXAMPLE 1:

FDCN01 CWA0 071530					
FCST BASED ON 071200 DATA VALID 080000 FOR USE 21-06					
FT	3000	6000	9000	12000	18000

YXC	3040-27	315143	316754	306761
YYC	3058-29	317246	317855	306358
YQL	2955-28	306845	307455	791159

When the forecast speed is less than 5 kt, the code group is "9900", which reads "light and variable".

Encoded wind speeds from 100 to 199 kt have 50 added to the direction code and 100 subtracted from the speed. Wind speeds that have had 50 added to the direction can be recognized when figures from 51 to 86 appear in the code. Since no such directions exist, (i.e., 510° to 860°) obviously they represent directions from 010° to 360°.

CANADA APPENDICES

Should the forecast wind speed be 200 kt or greater, the wind group is coded as 199 kt, that is, 7799 is decoded 270° at 199 kt or greater.

Examples of decoding FD winds and temperatures are as follows (the third and fourth examples are both for altitudes above 24,000 ft):

EXAMPLE	DECODED
9900 + 00	Wind light and variable, temperature 0°C.
2523	250°T at 23 kt.
791159	290°T (79 - 50 = 29) at 111 kt (11 + 100 = 111), temperature -59°C.
859950	350°T (85 - 50 = 35) at 199 kt or greater, temperature -50°C.

Forecasts in digital form of the winds and the temperatures aloft (FB) are currently available over the phone. They have a similar format to FD forecasts but are updated four times a day and include other improvements. FD forecasts will continue to be available but will gradually be replaced by FB forecasts.

3.10 SURFACE WEATHER MAPS

COLOR	SYMBOL	DESCRIPTION
BLUE	H	High pressure center
RED	L	Low pressure center
BLUE		Cold front
BLUE		Cold front aloft
RED		Warm front
RED		Warm front aloft
RED / BLUE		Stationary front
PURPLE		Occluded front
BLUE		Cold frontogenesis
RED		Warm frontogenesis
RED / BLUE		Stationary frontogenesis
BLUE		Cold frontolysis

**CANADA
APPENDICES**

COLOR	SYMBOL	DESCRIPTION
RED		Warm frontolysis
RED / BLUE		Stationary frontolysis
PURPLE		Occluded frontolysis
PURPLE		Squall line
PURPLE		Trough
BLUE / RED		Trowal

The following is a list of things to keep in mind when reading surface weather maps:

- Check the time of the map, make sure that it is the latest one available.
- Always remember that weather moves. A map gives you a static picture of weather conditions over a large area at a specific time. Always use a map along with the latest reports and forecasts.
- The curving lines on the map which form patterns like giant thumb-prints are called isobars. Joining points of equal sea level pressure, isobars outline the areas of High and Low pressure, marked H and L, respectively.
- The winds at 2000' AGL blow roughly parallel to the isobars — in a clockwise direction around Highs and counter-clockwise around Lows. Wind speeds vary with the distance between isobars. Where the lines are close together, moderate to strong winds can be expected; where they are far apart, light variable winds are expected.
- The red and blue lines are called fronts. These lines indicate the zones of contact between large air masses with differing physical properties — cold vs. warm, dry vs. moist, etc. Blue lines are for cold fronts — cold air advancing. Red lines are for warm fronts — warm air advancing. Alternate red and blue lines are for quasi-stationary fronts — neither warm air nor cold air advancing. Hook marks in red and blue are for trowals — trough of warm air aloft. A purple line is called an Occluded Front — where a cold front has overtaken a warm front. Solid colored lines are fronts which produce air mass changes at the ground level as well as in the upper air. Dashed colored lines represent “upper air” fronts — they also are important. Along all active fronts one usually encounters clouds and precipitation.
- When colors cannot be used to distinguish the various kinds of fronts, monochromatic symbols are used.

3.11 UPPER LEVEL CHARTS — ANAL

Upper level charts depict two forms of data: actual and forecast. Actual measured conditions are represented on analyzed charts (ANAL). These charts show conditions as they were at a specific

CANADA APPENDICES

time in the past. Prognostic charts (PROG) show forecast conditions for a specific time in the future. Always check the map label for the type, date and valid time of a chart.

3.11.1 Upper Level Analysis Charts

Meteorological parameters in the upper atmosphere are measured twice a day (0000Z and 1200Z). The data are plotted and analyzed on constant pressure level charts. These charts always indicate past conditions. The 850 hPa (5000 feet), 700 hPa (10,000 feet), 500 hPa (18,000 feet), and 250 hPa (34,000 feet) analyzed charts are available in Canada and are generally in weather offices and on NAV CANADA's aviation weather web site (AWWS) about three hours after the data are recorded.

The maps have various fields analyzed.

a. **Height**

The solid lines (contours) on all the charts represent the approximate height of the pressure level indicated by the map. The contours are labeled in decameters (10's of meters) such that on a 500 hPa map, 540 means 5400m and on a 250 hPa map, 020 means 10,200m. Contours are spaced 60m (6 decameters) apart except at 250 hPa where the spacing is 120m.

b. **Temperature**

Temperature is analyzed on the 850 and 700 hPa charts only. Dashed lines are drawn at 5°C intervals and are labeled 5, 0, -5, etc. Temperatures at 500 and 250 hPa are obtained by reading the number in the upper left corner of each of the station plots.

c. **Wind Direction**

Wind direction may be determined at any point by using the height contours. The wind generally blows parallel to the contours and the direction is determined by keeping the "wind at your back with low heights to the left". The plotted wind arrows also provide the actual wind direction at the stations.

d. **Wind Speed**

Wind speed is inversely proportional to the spacing of the height contours. If the contours are close together, the winds are strong; if far apart, the winds are light. The plotted wind arrows also provide the wind speed.

On the 250 hPa chart, wind speeds are analyzed using dashed lines for points with the same wind speed (isotachs). The isotachs are analyzed by a computer and are drawn at 30 kt intervals starting at 30 kt.

NOTE: Computer analyzed charts have the analyzed parameters smoothed to some extent.

3.11.2 Upper Level Prognostic Charts

Upper level wind and temperature charts are issued by the world area forecast centre (WAFC), through the U.S. National Oceanic and Atmospheric Administration's (NOAA) National Weather Service (NWS) in Washington, D.C. Winds are depicted for FL240, FL340, FL390 and FL450

**CANADA
APPENDICES**

using arrow shafts with pennants (50 kt each), full feathers (10 kt each) and half feathers (5 kt each). The orientation of the shaft indicates wind direction (degree true).

Temperatures ($^{\circ}\text{C}$) are presented in bold type at fixed grid points for the flight level. All temperatures are negative unless otherwise noted.

Wind and temperature information from these charts, in conjunction with the upper level wind and temperature forecast (FD) and significant weather charts (SIGWX), can be used to determine wind shear and other salient information such as the probability of CAT over given points. Remember, the wind speed is normally highest at the tropopause and decreases above and below at a relatively constant rate.

Section of an Upper Level Wind and Temperature Chart

CANADA APPENDICES

**CANADA
APPENDICES**

The Canadian Meteorological Aviation Centres (CMACs) issue a series of significant weather prognostic charts for lower levels, from 700 to 400 hPa (FL100 to FL240). They use the same criteria as the significant weather prognostic high level charts plus the following:

- a. moderate to severe icing;
- b. cloud layers of significance;
- c. marked mountain waves;
- d. freezing level line (0°C) at 5000-ft intervals, and labeled in hundreds of feet; and/or
- e. surface positions and direction of motion (in knots) of highs, lows, and other significant features (front, trough).

Symbols used on the Significant Weather Prognostic Charts by the CMAC:

SIGNIFICANT WEATHER SYMBOLS			
	Boundary of an Area of Significant Cloud		Boundary of an Area of Turbulence
	Moderate Turbulence*		Thunderstorm
	Severe Turbulence*		Severe Line Squall
	Light icing*		Hurricane
			Tropical Storm
			Dust or Sand Storm

CANADA APPENDICES

SIGNIFICANT WEATHER SYMBOLS

Moderate icing*

Severe icing*

* an abbreviation for the type of turbulence, or icing is placed below the symbol
(for ex. CAT for Clear Air Turbulence, or MXD for Mixed Icing).

CLOUD

Cloud types are represented by the conventional abbreviation, cloud amount are indicated as BKN or OVC, and height of base and tops by the convention illustrated:

BKN AC 240 Altocumulus,
XX base below chart
level, tops 24,000
feet.

ABBREVIATIONS

CAT — Clear Air Turbulence Lyr — Layers

CANADA APPENDICES

3.12.2 High-Level Charts

These charts, produced for the mid and high levels, show occurring or forecast weather conditions considered to be of concern to aircraft operations. The world area forecast centre (WAFC), through the U.S. National Oceanic and Atmospheric Administration's (NOAA) National Weather Service (NWS) issues a chart depicting forecast weather conditions between FL250 and FL630. Each chart includes a background that depicts the major bodies of land and water for the related region along with a few letters that correspond to the first letters of the names of cities located at the adjacent black dot. The meteorological conditions depicted and the symbols used are:

- a. **Active thunderstorms** — The cumulonimbus (CB) symbol is used when thunderstorms occur, or are forecast to occur, over a widespread area, along a line, embedded in other

CANADA
APPENDICES

cloud layers, or when concealed by a hazard. The amounts and the spatial coverage (in brackets) are indicated as:

- (i) ISOL (isolated) — for individual CBs (less than 50%)
- (ii) OCNL (occasional) — for well-separated CBs (50-75% inclusive)
- (iii) FRQ (frequent) — for CBs with little or no separation (greater than 75%)

NOTE: The definitions of the above terms, as used in ICAO charts, differ from those used for national SIGMET, AIRMET and GFA. The ICAO definitions involve 25% greater coverage in all cases. Some charts may include SCT which refers to 25-50% areal coverage. In addition, ISOL is used by ICAO while ISOL is used in national forecasts.

Embedded CBs may or may not be protruding from the cloud or haze layer. The following abbreviations are used to indicate the presence of CBs: ISOL embedded CB, OCNL embedded CB, FRQ embedded CB and FRQ CB. All other clouds are depicted using OKTA amounts, followed by the cloud type. In certain cases the abbreviation LYR (layer or layered) is used to indicate cloud structure.

- b. **Cloud heights** — When cloud tops or bases exceed the upper or lower limits of a significant weather prognostic chart, an XXX symbol is used on the appropriate side of the dividing line. Consider, for example, the significant weather prognostic chart that extends from FL250 to FL630. If well separated embedded CBs based below FL250 and topped at FL450 were present, this would be depicted as follows:

The scalloped line indicates the area in which the conditions written inside apply.

- c. **Tropopause height** — Tropopause heights are depicted as flight levels, except when defining areas of very flat slope, and are enclosed in a rectangular box. The center of the box represents the grid point being forecast.

- d. **Jet streams** — The height and speed of jet streams having a core speed of 80 kt or more are shown oriented to true north using arrows with pennants and feathers for speed, and spaced sufficiently close to give a good indication of speed and/or height changes. A double-hatched line across the jet stream core indicates a speed increase or decrease. The

CANADA APPENDICES

double-hatched line indicates 20 kt changes at 100 kt, 120 kt, 140 kt, or higher. For example, a 120 kt jet stream initially at FL420 dropping to 80 kt at FL370 would be depicted as:

The vertical depth of the jet stream is depicted by two numbers, indicating the height of the 80-kt isotach in hundreds of feet ASL. In the above example, the 80-kt isotach is forecast to be based at FL320 and topped at FL520. Only jet streams with a speed of 120 kt or more will contain vertical depth information.

- e. **Turbulence** — Areas of moderate or severe turbulence in cloud or clear air are depicted using heavy dashed lines, height symbols, a  for moderate turbulence and a  for severe. Wind shear and mountain wave turbulence are included; convective turbulence is not. For example, an area of moderate turbulence between FL280 and FL360 would be shown as:

- f. **Severe squall lines** — Severe squall lines are depicted using the symbol  and oriented to true north with a representative length. An area of frequent CB associated with a squall line would be shown as:

- g. **Icing and hail** — Icing and hail are not specifically noted but rather the following statement is included in the label on each chart:

SYMBOL CB IMPLIES HAIL, MODERATE OR GREATER TURBULENCE AND ICING

- h. **Widespread sandstorm or duststorm** — Areas of these conditions are shown using a scalloped line, height symbol and a . For example:

CANADA
APPENDICES

- i. **Tropical cyclones** — The symbol  is used to depict tropical cyclones and, if any of the previous criteria are met, these will be included. For example, an area of frequent CBs between 10,000 feet and 50,000 feet with an associated tropical storm named “William” would be shown as:

Significant weather prognostic charts depicting the tropical cyclone symbol will have a statement to the effect that the latest tropical cyclone advisory, rather than the tropical cyclone’s prognostic position on the chart, is to be given public dissemination.

- j. **Volcanic eruption** — Information on the location of volcanic eruptions that are producing ash clouds of significance to aircraft operations is shown as follows: the volcanic eruption symbol is shown at the location of the volcano; on the side of the chart, a box is shown containing the volcano eruption symbol, the name and international number of the volcano (if known), the latitude/longitude, and date and time of the first eruption (if known). Check SIGMET and NOTAM or ASHTAM for volcanic ash. The symbol is as follows, and may be depicted in red on color charts:

- k. **Radioactive material in the atmosphere** — Information on the location of a release of radioactive materials into the atmosphere that is of significance to aircraft operations is shown as follows: the radioactivity symbol at the site of the accident; on the side of the chart, in a box containing the radioactivity symbol, latitude/longitude of the site of the accident, date and time of the release and a reminder to users to check NOTAM for the area

CANADA APPENDICES

concerned. The symbol, in black on a yellow circular background when depicted in color, is as follows:

3.13 VOLCANIC ASH PRODUCTS

- a. **ICAO products** — The Montreal volcanic ash advisory centre (VAAC), a unit of Environment Canada, is an International Civil Aviation Organization (ICAO) designated centre responsible for issuing specialized advisories when volcanic ash is present in Canadian-controlled airspace. VAAC Montreal issues volcanic ash advisories (VAA) on the horizontal and vertical extent of volcanic clouds, their altitude, and expected movements. These advisories are based on satellite observations, pilot reports, and weather forecast and dispersion models. VAA are issued as both text and graphic products and are available via the VAAC Montreal Web site at https://weather.gc.ca/eer/vaac/index_e.html.
- b. **Model simulations of volcanic ash** — In addition to the official VAA described in the previous paragraph, results from simulations of the volcanic ash dispersion model, known as MLDPn (an abbreviation that stands for modèle langrangien de dispersion de particules d'ordre n), are also available at https://weather.gc.ca/eer/vaac/index_e.html.

Forecasts of concentrations of ash and the expected paths of volcanic clouds are generated when volcanic ash threatens Canadian-controlled airspace.

Such simulations are also performed for active volcanos whose eventual eruption could affect Canadian-controlled airspace. These MLDPn outputs are produced automatically using hypothetical eruption start times that are three hours apart. Forecast ash concentrations are presented as prognostic charts composed of four panels.

The Figure, shown below, shows the average concentration for three layers expressed in terms of flight levels (in hundreds of feet) as well as the ash mass loading for the whole atmospheric column: surface to FL200 (upper left-hand panel), FL200–FL350 (upper right-hand panel), FL350–FL600 (lower left-hand panel), and ash mass loading (lower right-hand panel).

The time at which the run starts is indicated in the legend box in the lower, left-hand portion of the image. The date and time of forecast validity are indicated on the clock in the lower, right-hand portion of the image. The results are based on the execution of the last global numerical weather prediction (NWP) model using either 0000 or 1200 UTC data.

The volcano of interest is at the centre of the image. The average volcanic ash concentration in the atmospheric layer is depicted as very low, low, moderate, or high. The isolines are for 1, 10, 100 and 1000 $\mu\text{g}/\text{m}^3$ (micrograms per cubic metre). The areas between the isolines are enhanced as follows:

**CANADA
APPENDICES**

1. 1–10 $\mu\text{g}/\text{m}^3$ is indicated by blue stippling;
2. 10–100 $\mu\text{g}/\text{m}^3$ is indicated by green stippling;
3. 100–1000 $\mu\text{g}/\text{m}^3$ is indicated by yellow stippling; and
4. > 1000 $\mu\text{g}/\text{m}^3$ is indicated by orange stippling.

The total ash mass loading is also depicted as very low, low, moderate, or high, with isolines for 0.01; 0.1; 1 and 10 g/m^2 .

CAUTION: Users are reminded to consult the latest significant meteorological information (SIGMET) and official ICAO products for updates on the position and vertical extent of the volcanic ash warning area. Even light (LGT) concentrations constitute a potential danger to aviation. Turbine engine flameouts have been attributed to light volcanic ash clouds located up to 1000 NM from the source.

CANADA APPENDICES

Figure 13.1 — Example of Volcanic Ash Forecast Caused by a Hypothetical Eruption

3.14 SPACE WEATHER INFORMATION SERVICE

3.14.1 Introduction

Civil aviation may be affected by space weather phenomena, notably with respect to:

- high-frequency (HF) radio communications;
- global navigation satellite system-based (GNSS-based) navigation and surveillance;
- satellite communications; and
- increased exposure to radiation aboard aircraft.

CANADA APPENDICES

ICAO has therefore organized a space weather information service, whereby advisories will be disseminated through the aeronautical fixed service (AFS), including the aeronautical fixed telecommunications network (AFTN) and the Air Traffic Services Message Handling System (AMHS), in cases of moderate or severe impacts on the four domains identified above.

3.14.2 Nature of the Disturbances

Space weather events are caused by solar flares and particles ejected from the sun. The electromagnetic radiation from solar flares causes a shortwave fadeout (i.e. an increased absorption of HF radio waves on the dayside of the earth that lasts for up to an hour). The particles arriving from the sun are guided to high latitudes, where they produce polar cap absorption and auroral absorption, which cause a loss of HF radio communications that can last for many hours and recur for several days. In addition, ionospheric disturbances at mid-latitudes can reduce the maximum useable frequency for HF radio communications.

Ionospheric disturbances can also interfere with the radio signals used for global navigation satellite system (GNSS) positioning and navigation. Increases in the total electron content (TEC) of the ionosphere lead to an increase in the transit time of the GNSS signal, producing position errors in GNSS receivers. Scintillation (rapid variations in amplitude or phase) of the radio signals can cause GNSS receivers to “lose lock” on the radio signals and give false information or no information at all. Satellite communications (SATCOM) signals also pass through the ionosphere and can be affected by scintillation.

High-energy particles from the sun are guided by the earth’s magnetic field and enter the atmosphere in polar regions. The latitudes affected depend on the energy of the particles. Most solar particles are absorbed by the atmosphere, but the high-energy particles that interact with atmospheric particles trigger secondary ionizing particle cascades, which increase radiation aboard aircraft. The dose from these particles is greatest at the highest aviation altitudes and decreases with reduced altitude.

3.14.3 The ICAO Service Advisories

Space weather service providers will issue an advisory when conditions exceed thresholds for moderate (MOD) or severe (SEV) events. The parameters and thresholds used to define MOD and SEV events are listed in the first edition (2019) of the *ICAO Manual on Space Weather Information in Support of International Air Navigation* (Doc 10100).

The space weather advisories will contain information about current conditions, as well as forecast levels for 6 hours, 12 hours, 18 hours, and 24 hours ahead.

Separate advisories will be issued for each of the following three phenomena:

- a. HF radio communications (HF COM)
- b. GNSS-based navigation (GNSS)
- c. Radiation at aircraft altitudes (RADIATION)

Advisories for satellite communications (SATCOM) will not be provided by any space weather centers as further work is required to establish operationally relevant thresholds for aviation SATCOM.

CANADA APPENDICES

Affected geographic areas are referenced by their latitudes and longitudes, and above flight levels (ABV FL) for radiation. Abbreviations are also used:

- a. High latitudes northern hemisphere (N9000–N6000): HNH
- b. Mid-latitudes northern hemisphere (N6000–N3000): MNH
- c. Equatorial latitudes northern hemisphere (N3000–N0000): EQN
- d. Equatorial latitudes southern hemisphere (S0000–S3000): EQS
- e. Mid-latitudes southern hemisphere (S3000–S6000): MSH
- f. High latitudes southern hemisphere (S6000–S9000): HSH

NOTE: Some advisories may be for the whole daylight side of Earth (daylight side).

Advisories will be issued as soon as an increase above the MOD or SEV thresholds are detected. Advisories are updated as often as necessary, but at least every 6 hours, until such time as the elevated space weather levels are no longer detected or no longer expected. At that time, an advisory will be issued stating that the event is finished, with the message that no elevated space weather is expected (NO SWX EXP).

Test or exercise advisories may be issued.

Space weather advisory information relevant to the whole route should be supplied to operators and flight crew members as part of meteorological information.

3.14.4 Response to Advisories

The ICAO service does not define the operational responses to space weather events. Such responses are the responsibility of aircraft operators, who may choose to have operational procedures in place to be ready in case of space weather events. Guidance on the use of space weather advisory information is provided in Chapter 4 of the *ICAO Manual on Space Weather Information in Support of International Air Navigation* (Doc 10100, 2019). (Not published herein.)

3.14.5 Space Weather Advisory Message

A space weather advisory message has the following format:

Table 14.1 — Space Weather Advisory Message Format

(1)	WMO Header (FNXX01, WMO location indicator, UTC date-time of issue of the message)
(2)	SWX ADVISORY (message type)
(3)	STATUS (either test (TEST) or exercise (EXER) if required)
(4)	DTG (Time of Origin – Year/month/date/time in UTC)
(5)	SWXC (name of Space Weather Centre)
(6)	ADVISORY NR (advisory number; unique sequence for each space weather effect: HFCOM, GNSS, RADIATION, SATCOM)

**CANADA
APPENDICES**

Table 14.1 — Space Weather Advisory Message Format (continued)

(7)	NR RPLC (number of the previously issued advisory being replaced)
(8)	SWX EFFECT (effect and intensity of space weather phenomenon)
(9)	OBS (or FCST) SWX (Date and time [in UTC] and description of spatial extent of observed or forecast space weather phenomenon)
(10)	FCST SWX + 6 HR (Date-time [in UTC] of forecast spatial extent of space weather event)
(11)	FCST SWX + 12 HR (as above)
(12)	FCST SWX + 18 HR (as above)
(13)	FCST SWX + 24 HR (as above)
(14)	RMK (NIL or free text)
(15)	NXT ADVISORY (Yearmonth/date/time [in UTC] or NO FURTHER ADVISORIES)

SECTION 1. METEOROLOGY**

7-1-1 NATIONAL WEATHER SERVICE AVIATION WEATHER SERVICE PROGRAM

- a. Weather service to aviation is a joint effort of the National Oceanic and Atmospheric Administration (NOAA), the National Weather Service (NWS), the Federal Aviation Administration (FAA), Department of Defense, and various private sector aviation weather service providers. Requirements for all aviation weather products originate from the FAA, which is the Meteorological Authority for the U.S.
- b. NWS meteorologists are assigned to all air route traffic control centers (ARTCC) as part of the Center Weather Service Units (CWSU) as well as the Air Traffic Control System Command Center (ATCSCC). These meteorologists provide specialized briefings as well as tailored forecasts to support the needs of the FAA and other users of the NAS.
- c. Aviation Products
 1. The NWS maintains an extensive surface, upper air, and radar weather observing program; and a nationwide aviation weather forecasting service.
 2. Airport observations (METAR and SPECI) supported by the NWS are provided by automated observing systems.
 3. Terminal Aerodrome Forecasts (TAF) are prepared by 123 NWS Weather Forecast Offices (WFOs) for over 700 airports. These forecasts are valid for 24 or 30 hours and amended as required.
 4. Inflight aviation advisories (for example, Significant Meteorological Information (SIGMETs) and Airmen's Meteorological Information (AIRMETs)) are issued by three NWS Meteorological Watch Offices; the Aviation Weather Center (AWC) in Kansas City, MO, the Alaska Aviation Weather Unit (AAWU) in Anchorage, AK, and the WFO in Honolulu, HI. Both the AWC and the AAWU issue area forecasts (FA) for selected areas. In addition, NWS meteorologists assigned to most ARTCCs as part of the Center Weather Service Unit (CWSU) provide Center Weather Advisories (CWAs) and gather weather information to support the needs of the FAA and other users of the system.
 5. Several NWS National Centers for Environmental Prediction (NCEP) provide aviation specific weather forecasts, or select public forecasts which are of interest to pilots and operators.
 - (a) The Aviation Weather Center (AWC) displays a variety of domestic and international aviation forecast products over the Internet at aviationweather.gov.
 - (b) The NCEP Central Operations (NCO) is responsible for the operation of many numerical weather prediction models, including those which produce the many wind and temperature aloft forecasts.
 - (c) The Storm Prediction Center (SPC) issues tornado and severe weather watches along with other guidance forecasts.
 - (d) The National Hurricane Center (NHC) issues forecasts on tropical weather systems (for example, hurricanes).

UNITED STATES
SECTION 1. METEOROLOGY

- (e) The Space Weather Prediction Center (SWPC) provides alerts, watches, warnings and forecasts for space weather events (for example, solar storms) affecting or expected to affect Earth's environment.
- (f) The Weather Prediction Center (WPC) provides analysis and forecast products on a national scale including surface pressure and frontal analyses.
- 6. NOAA operates two Volcanic Ash Advisory Centers (VAAC) which issue forecasts of ash clouds following a volcanic eruption in their area of responsibility.
- 7. Details on the products provided by the above listed offices and centers is available in FAA Advisory Circular 00-45, Aviation Weather Services.
- d. Weather element values may be expressed by using different measurement systems depending on several factors, such as whether the weather products will be used by the general public, aviation interests, international services, or a combination of these users. FIG 7-1-1 provides conversion tables for the most used weather elements that will be encountered by pilots.

7-1-2 FAA WEATHER SERVICES

- a. The FAA provides the Flight Service program, which serves the weather needs of pilots through its flight service stations (FSS) (both government and contract via 1-800-WX-BRIEF) and via the Internet, through Leidos Flight Service.
- b. The FAA maintains an extensive surface weather observing program. Airport observations (METAR and SPECI) in the U.S. are provided by automated observing systems. Various levels of human oversight of the METAR and SPECI reports and augmentation may be provided at select larger airports by either government or contract personnel qualified to report specified weather elements that cannot be detected by the automated observing system. The requirements to issue SPECI reports are detailed in TBL 7-1-1.

Table 7-1-1

SPECI Issuance Table		
1	Wind Shift	Wind direction changes by 45° or more, in less than 15 minutes, and the wind speed is 10 kt or more throughout the wind shift.
2	Visibility	The surface visibility (as reported in the body of the report): – Decreases to less than 3 sm, 2 sm, 1 sm, ½ sm, ¼ sm or the lowest standard instrument approach procedure (IAP) minimum.¹ – Increases to equal to or exceed 3 sm, 2 sm, 1 sm, ½ sm, ¼ sm or the lowest standard IAP minimum.¹ ¹ As published in the U.S. Terminal Procedures. If none published, use ½ sm.

UNITED STATES
SECTION 1. METEOROLOGY

Table 7-1-1 (continued)

3	RVR	The highest value from the designated RVR runway decreases to less than 2,400 ft during the preceding 10 minutes; or, if the RVR is below 2,400 ft, increases to equal to or exceed 2,400 ft during the preceding 10 minutes. U.S. military stations may not report a SPECI based on RVR.
4	Tornado, Funnel Cloud, or Waterspout	– Is observed. – Disappears from sight or ends.
5	Thunderstorm	– Begins (a SPECI is not required to report the beginning of a new thunderstorm if one is currently reported). – Ends.
6	Precipitation	– Hail begins or ends. – Freezing precipitation begins, ends, or changes intensity. – Ice pellets begin, end, or change intensity. – Snow begins, ends, or changes intensity.
7	Squalls	When a squall occurs. (Wind speed suddenly increases by at least 16 knots and is sustained at 22 knots or more for at least one minute.)
8	Ceiling	The ceiling changes¹ through: – 3,000 ft. – 1,500 ft. – 1,000 ft. – 500 ft. – <i>The lowest standard IAP minimum.</i>² ¹ “Ceiling change” means that it forms, dissipates below, decreases to less than, or, if below, increases to equal or exceed the values listed. ² As published in the U.S. Terminal Procedures. If none published, use 200 ft.
9	Sky Condition	A layer of clouds or obscurations aloft is present below 1,000 ft and no layer aloft was reported below 1,000 ft in the preceding METAR or SPECI.
10	Volcanic Eruption	When an eruption is first noted.

UNITED STATES
SECTION 1. METEOROLOGY

Table 7-1-1 (continued)

11	Aircraft Mishap	Upon notification of an aircraft mishap, ¹ unless there has been an intervening observation. ¹ "Aircraft mishap" is an inclusive term to denote the occurrence of an aircraft accident or incident.
12	Miscellaneous	Any other meteorological situation designated by the responsible agency of which, in the opinion of the observer, is critical.

c. Other Sources of Weather Information

1. Weather and aeronautical information are available from numerous private industry sources on an individual or contract pay basis. Prior to every flight, pilots should gather all information vital to the nature of the flight. Pilots can receive a regulatory compliant briefing without contacting Flight Service. Pilots are encouraged to use automated resources and review AC 91-92, Pilot's Guide to a Preflight Briefing, for more information.

UNITED STATES
SECTION 1. METEOROLOGY

2. Pilots can access Leidos Flight Services via the Internet at <http://www.1800wxbrief.com>. Pilots can receive preflight weather data and file VFR and IFR flight plans.

JEPPESSEN WEATHER SERVICES

Jeppesen provides a robust worldwide weather service. The service includes access to U.S. NWS and U.K. Met Office text weather reports, aviation specific graphic weather maps, and custom forecasts and briefing from our staff of professional aviation meteorologists. Jeppesen provides access to our weather service through pc and web based applications as well as our UNIX based dispatch client. Weather maps can be overlaid with planned routes and weather reports can be sent directly to the aircraft via ACARS and SatCom Direct. Our proprietary Vector Weather Graphics allows for enhanced overlays and visualization of weather phenomenon. Worldwide weather maps include access to the following map types:

- U.S. and Canada NEXRAD Single Site Radar
- U.S. and Canada NEXRAD Radar Mosaic, including winter mosaic that depicts snow, freezing rain and rain
- U.S. NEXRAD Radar Forecasts (6 hours)
- U.S. Low Level Significant Weather Forecasts
- Worldwide Infrared and Visible Satellite Imagery
- Worldwide Upper Level Wind and Temp Analyses and Forecasts
- Worldwide Turbulence Analyses and Forecasts
- Worldwide Icing Analyses and Forecasts
- Worldwide Ceiling and Visibility Analyses and Forecasts
- Worldwide High Level Significant Weather Forecasts
- Worldwide Surface Analyses and Forecasts
- Worldwide Weather Depiction
- Worldwide Hurricane/Typhoon Tracks.

Jeppesen provides a limited set of free weather on our web site at www.jeppesen.com/weather as well as additional information about our worldwide weather subscription service. For additional information, please contact a sales representative at 1-800-358-6468.

7-1-3 USE OF AVIATION WEATHER PRODUCTS

- a. Air carriers and operators certificated under the provisions of 14 CFR Part 119 are required to use the aeronautical weather information systems defined in the Operations Specifications issued to that certificate holder by the FAA. These systems may utilize basic FAA/ National Weather Service (NWS) weather services, contractor- or operator-proprietary weather services and/or Enhanced Weather Information System (EWINS) when approved in the Operations Specifications. As an integral part of this system approval, the procedures for collecting, producing and disseminating aeronautical weather information, as well as the

UNITED STATES

SECTION 1. METEOROLOGY

crew member and dispatcher training to support the use of system weather products, must be accepted or approved.

- b. Operators not certificated under the provisions of 14 CFR Part 119 are encouraged to use FAA/NWS products through Flight Service Stations, Leidos Flight Service, and/or Flight Information Services-Broadcast (FIS-B).
- c. The suite of available aviation weather product types is expanding, with the development of new sensor systems, algorithms and forecast models. The FAA and NWS, supported by various weather research laboratories and corporations under contract to the Government, develop and implement new aviation weather product types. The FAA's NextGen Aviation Weather Research Program (AWRP) facilitates collaboration between the NWS, the FAA, and various industry and research representatives. This collaboration ensures that user needs and technical readiness requirements are met before experimental products mature to operational application.
- d. The AWRP manages the transfer of aviation weather R&D to operational use through technical review panels and conducting safety assessments to ensure that newly developed aviation weather products meet regulatory requirements and enhance safety.
- e. The AWRP review and decision-making process applies criteria to weather products at various stages. The stages are composed of the following:
 - 1. Sponsorship of user needs.
 - 2. R&D and controlled testing.
 - 3. Experimental application.
 - 4. Operational application.
- f. Pilots and operators should be aware that weather services provided by entities other than FAA, NWS, or their contractors may not meet FAA/NWS quality control standards. Hence, operators and pilots contemplating using such services should request and/or review an appropriate description of services and provider disclosure. This should include, but is not limited to, the type of weather product (for example, current weather or forecast weather), the currency of the product (that is, product issue and valid times), and the relevance of the product. Pilots and operators should be cautious when using unfamiliar products, or products not supported by FAA/NWS technical specifications.

NOTE: *When in doubt, consult with a FAA Flight Service Station Specialist.*

- g. In addition, pilots and operators should be aware there are weather services and products available from government organizations beyond the scope of the AWRP process mentioned earlier in this section. For example, governmental agencies such as the NWS and the Aviation Weather Center (AWC), or research organizations such as the National Center for Atmospheric Research (NCAR) display weather "model data" and "experimental" products which require training and/or expertise to properly interpret and use. These products are developmental prototypes that are subject to ongoing research and can change without notice. Therefore, some data on display by government organizations, or government data

UNITED STATES

SECTION 1. METEOROLOGY

on display by independent organizations may be unsuitable for flight planning purposes. Operators and pilots contemplating using such services should request and/or review an appropriate description of services and provider disclosure. This should include, but is not limited to, the type of weather product (for example, current weather or forecast weather), the currency of the product (i.e., product issue and valid times), and the relevance of the product. Pilots and operators should be cautious when using unfamiliar weather products.

NOTE: *When in doubt, consult with a FAA Flight Service Station Specialist.*

- h. With increased access to weather products via the public Internet, the aviation community has access to an over whelming amount of weather information and data that support self-briefing. FAA AC 00-45 (current edition) describes the weather products distributed by the NWS. Pilots and operators using the public Internet to access weather from a third party vendor should request and/or review an appropriate description of services and provider disclosure. This should include, but is not limited to, the type of weather product (for example, current weather or forecast weather), the currency of the product (i.e., product issue and valid times), and the relevance of the product. Pilots and operators should be cautious when using unfamiliar weather products and when in doubt, consult with a Flight Service Specialist.
- i. The development of new weather products, coupled with the termination of some legacy textual and graphical products may create confusion between regulatory requirements and the new products. All flight-related, aviation weather decisions must be based on all available pertinent weather products. As every flight is unique and the weather conditions for that flight vary hour by hour, day to day, multiple weather products may be necessary to meet aviation weather regulatory requirements. Many new weather products now have a Precautionary Use Statement that details the proper use or application of the specific product.
- j. The FAA has identified three distinct types of weather information available to pilots and operators.
 - 1. **Observations.** Raw weather data collected by some type of sensor suite including surface and airborne observations, radar, lightning, satellite imagery, and profilers.
 - 2. **Analysis.** Enhanced depiction and/or interpretation of observed weather data.
 - 3. **Forecasts.** Predictions of the development and/or movement of weather phenomena based on meteorological observations and various mathematical models.
- k. Not all sources of aviation weather information are able to provide all three types of weather information. The FAA has determined that operators and pilots may utilize the following approved sources of aviation weather information:
 - 1. **Federal Government.** The FAA and NWS collect raw weather data, analyze the observations, and produce forecasts. The FAA and NWS disseminate meteorological observations, analyses, and forecasts through a variety of systems. In addition, the Federal Government is the only approval authority for sources of weather observations; for example, contract towers and airport operators may be approved by the Federal Government to provide weather observations.

UNITED STATES

SECTION 1. METEOROLOGY

2. **Enhanced Weather Information System (EWINS).** An EWINS is an FAA authorized, proprietary system for tracking, evaluating, reporting, and forecasting the presence or lack of adverse weather phenomena. The FAA authorizes a certificate holder to use an EWINS to produce flight movement forecasts, adverse weather phenomena forecasts, and other meteorological advisories. For more detailed information regarding EWINS, see the Aviation Weather Services Advisory Circular 00-45 and the Flight Standards Information Management System 8900.1.
3. **Commercial Weather Information Providers.** In general, commercial providers produce proprietary weather products based on NWS/FAA products with formatting and layout modifications but no material changes to the weather information itself. This is also referred to as “repackaging.” In addition, commercial providers may produce analyses, forecasts, and other proprietary weather products that substantially alter the information contained in government-produced products. However, those proprietary weather products that substantially alter government-produced weather products or information, may only be approved for use by 14 CFR Part 121 and Part 135 certificate holders if the commercial provider is EWINS qualified.

NOTE: *Commercial weather information providers contracted by FAA to provide weather observations, analyses, and forecasts (e.g., contract towers) are included in the Federal Government category of approved sources by virtue of maintaining required technical and quality assurance standards under Federal Government oversight.*

7-1-4 GRAPHICAL FORECASTS FOR AVIATION (GFA)

- a. The GFA website is intended to provide the necessary aviation weather information to give users a complete picture of the weather that may affect flight in the continental United States (CONUS). The website includes observational data, forecasts, and warnings that can be viewed from 14 hours in the past to 15 hours in the future, including thunderstorms, clouds, flight category, precipitation, icing, turbulence, and wind. Hourly model data and forecasts, including information on clouds, flight category, precipitation, icing, turbulence, wind, and graphical output from the National Weather Service’s (NWS) National Digital Forecast Data (NDFD) are available. Wind, icing, and turbulence forecasts are available in 3,000 ft increments from the surface up to 30,000 ft MSL, and in 6,000 ft increments from 30,000 ft MSL to 48,000 ft MSL. Turbulence forecasts are also broken into low (below 18,000 ft MSL) and high (at or above 18,000 ft MSL) graphics. A maximum icing graphic and maximum wind velocity graphic (regardless of altitude) are also available. Built with modern geospatial information tools, users can pan and zoom to focus on areas of greatest interest. Target users are commercial and general aviation pilots, operators, briefers, and dispatchers.
- b. **Weather Products.**
 1. The Aviation Forecasts include gridded displays of various weather parameters as well as NWS textual weather observations, forecasts, and warnings. Icing, turbulence, and wind gridded products are three-dimensional. Other gridded products are two-dimensional and may represent a “composite” of a three-dimensional weather phenomenon or

UNITED STATES

SECTION 1. METEOROLOGY

a surface weather variable, such as horizontal visibility. The following are examples of aviation forecasts depicted on the GFA:

- (a) Terminal Aerodrome Forecast (TAF)
- (b) Ceiling & Visibility (CIG/VIS)
- (c) Clouds
- (d) Precipitation/Weather (PCPN/WX)
- (e) Thunderstorm (TS)
- (f) Winds
- (g) Turbulence
- (h) Ice

2. **Observations & Warnings (Obs/Warn).** The Obs/Warn option provides an option to display weather data for the current time and the previous 14 hours (rounded to the nearest hour). Users may advance through time using the arrow buttons or by clicking on the desired hour. Provided below are the Obs/Warn product tabs available on the GFA website:

- (a) METAR
- (b) Precipitation/Weather (PCPN/WX)
- (c) Ceiling & Visibility (CIG/VIS)
- (d) Pilot Weather Report (PIREP)
- (e) Radar & Satellite (RAD/SAT)

3. The GFA will be continuously updated and available online at **<http://aviation-weather.gov/gfa>**. Upon clicking the link above, select INFO on the top right corner of the map display. The next screen presents the option of selecting Overview, Products, and Tutorial. Simply select the tab of interest to explore the enhanced digital and graphical weather products designed to replace the legacy FA. Users should also refer to AC 00-45, *Aviation Weather Services*, for more detailed information on the GFA.

4. **GFA Static Images.** Some users with limited internet connectivity may access static images via the Aviation Weather Center (AWC) at: **<http://www.aviationweather.gov/gfa/plot>**. There are two static graphical images available, titled *Aviation Cloud Forecast* and *Aviation Surface Forecast*. The Aviation Cloud Forecast provides cloud coverage, bases, layers, and tops with Airmet Sierra for mountain obscuration and Airmet Zulu for icing overlaid. The Aviation Surface Forecast provides visibility, weather phenomena, and winds (including wind gusts) with Airmet Sierra for instrument flight rules conditions and Airmet Tango for sustained surface winds of 30 knots or more overlaid. These images are presented on ten separate maps providing forecast views for the entire CONUS on one and nine regional views which provide

UNITED STATES SECTION 1. METEOROLOGY

more detail for the user. They are updated every 3 hours and provide forecast snapshots for 3, 6, 9, 12, 15, and 18 hours into the future. (See FIG 7-1-2 and FIG 7-1-3.)

FIGURE 7-1-3
Aviation Cloud Forecast

7-1-5 PREFLIGHT BRIEFING

a. Flight Service is one of the primary sources for obtaining preflight briefings and to file flight plans by phone or the Internet. Flight Service Specialists are qualified and certificated as Pilot Weather Briefers by the FAA. They are not authorized to make original forecasts, but are authorized to translate and interpret available forecasts and reports directly into terms describing the weather conditions which you can expect along your flight route and at your destination. Prior to every flight, pilots should gather all information vital to the nature of the flight. Pilots can receive a regulatory compliant briefing without contacting Flight Service. Pilots are encouraged to use automated resources and review AC 91-92, Pilot's Guide to a Preflight Briefing, for more information. Pilots who prefer to contact Flight Service are encouraged to conduct a self-brief prior to calling. Conducting a self-brief before contacting Flight Service provides familiarity of meteorological and aeronautical conditions applicable to the route of flight and promotes a better understanding of weather information. Three basic types of preflight briefings (Standard, Abbreviated, and Outlook) are available to serve the pilot's specific needs. Pilots should specify to the briefer the type of briefing they want, along with their appropriate background information. This will enable the briefer to tailor the information to the pilot's intended flight. The following paragraphs describe the types of briefings available and the information provided in each briefing.

REFERENCE—AIM, Para 5-1-1, Preflight Preparation, for items that are required.

b. **Standard Briefing.** You should request a Standard Briefing any time you are planning a flight and you have not received a previous briefing or have not received preliminary information.

UNITED STATES

SECTION 1. METEOROLOGY

tion through online resources. International data may be inaccurate or incomplete. If you are planning a flight outside of U.S. controlled airspace, the briefer will advise you to check data as soon as practical after entering foreign airspace, unless you advise that you have the international cautionary advisory. The briefer will automatically provide the following information in the sequence listed, except as noted, when it is applicable to your proposed flight.

1. **Adverse Conditions.** Significant meteorological and/or aeronautical information that might influence the pilot to alter or cancel the proposed flight; for example, hazardous weather conditions, airport closures, air traffic delays, etc. Pilots should be especially alert for current or forecast weather that could reduce flight minimums below VFR or IFR conditions. Pilots should also be alert for any reported or forecast icing if the aircraft is not certified for operating in icing conditions. Flying into areas of icing or weather below minimums could have disastrous results.
2. **VFR Flight Not Recommended.** When VFR flight is proposed and sky conditions or visibilities are present or forecast, surface or aloft, that, in the briefer's judgment, would make flight under VFR doubtful, the briefer will describe the conditions, describe the affected locations, and use the phrase "*VFR flight not recommended.*" This recommendation is advisory in nature. The final decision as to whether the flight can be conducted safely rests solely with the pilot. Upon receiving a "*VFR flight not recommended*" statement, the non-IFR rated pilot will need to make a "go or no go" decision. This decision should be based on weighing the current and forecast weather conditions against the pilot's experience and ratings. The aircraft's equipment, capabilities and limitations should also be considered.

NOTE: *Pilots flying into areas of minimal VFR weather could encounter unforecasted lowering conditions that place the aircraft outside the pilot's ratings and experience level. This could result in spatial disorientation and/or loss of control of the aircraft.*

3. **Synopsis.** A brief statement describing the type, location and movement of weather systems and/or air masses which might affect the proposed flight.

NOTE: *These first 3 elements of a briefing may be combined in any order when the briefer believes it will help to more clearly describe conditions.*

4. **Current Conditions.** Reported weather conditions applicable to the flight will be summarized from all available sources; e.g., METARs/SPECIs, PIREPs, RAREPs. This element will be omitted if the proposed time of departure is beyond 2 hours, unless the information is specifically requested by the pilot.
5. **En Route Forecast.** Forecast en route conditions for the proposed route are summarized in logical order; i.e., departure/climbout, en route, and descent. (Heights are MSL, unless the contractions "AGL" or "CIG" are denoted indicating that heights are above ground.)
6. **Destination Forecast.** The destination forecast for the planned ETA. Any significant changes within 1 hour before and after the planned arrival are included.

UNITED STATES
SECTION 1. METEOROLOGY

7. **Winds Aloft.** Forecast winds aloft will be provided using degrees of the compass. The briefer will interpolate wind directions and speeds between levels and stations as necessary to provide expected conditions at planned altitudes. (Heights are MSL.) Temperature information will be provided on request.

8. **Notices to Air Missions (NOTAMs).**

- (a) Available NOTAM (D) information pertinent to the proposed flight, including special use airspace (SUA) NOTAMs for restricted areas, aerial refueling, and night vision goggles (NVG).

NOTE: *Other SUA NOTAMs (D), such as military operations area (MOA), military training route (MTR), and warning area NOTAMs, are considered "upon request" briefing items as indicated in paragraph 7-1-4b10(a).*

- (b) Prohibited Areas P-40, P-49, P-56, and the special flight rules area (SFRA) for Washington, DC.
- (c) FSS briefers do not provide FDC NOTAM information for special instrument approach procedures unless specifically asked. Pilots authorized by the FAA to use special instrument approach procedures must specifically request FDC NOTAM information for these procedures.

NOTE:

1. *NOTAM information may be combined with current conditions when the briefer believes it is logical to do so.*
2. *Airway NOTAMs, procedural NOTAMs, and NOTAMs that are general in nature and not tied to a specific airport/facility (for example, flight advisories and restrictions, open duration special security instructions, and special flight rules areas) are briefed solely by pilot request. For complete flight information, pilots are urged to review the Domestic Notices and International Notices found in the External Links section of the Federal NOTAM System (FNS) NOTAM Search System and the Chart Supplement U.S. In addition to obtaining a briefing.*

9. **ATC Delays.** Any known ATC delays and flow control advisories which might affect the proposed flight.

10. **Pilots may obtain the following from flight service station briefers upon request:**

- (a) Information on SUA and SUA-related airspace, except those listed in paragraph 7-1-4b8.

NOTE:

1. *For the purpose of this paragraph, SUA and related airspace includes the following types of airspace: alert area, military operations area (MOA), warning area, and air traffic control assigned airspace (ATCAA). MTR data includes the following types of airspace: IFR training routes (IR), VFR training routes (VR), and slow training routes (SR).*

UNITED STATES
SECTION 1. METEOROLOGY

2. Pilots are encouraged to request updated information from ATC facilities while in flight.

- (b) A review of airway NOTAMs, procedural NOTAMs, and NOTAMs that are general in nature and not tied to a specific airport/facility (for example, flight advisories and restrictions, open duration special security instructions, and special flight rules areas), Domestic Notices and International Notices. Domestic Notices and International Notices are found in the External Links section of the Federal NOTAM System (FNS) NOTAM Search System.
 - (c) Approximate density altitude data.
 - (d) Information regarding such items as air traffic services and rules, customs/immigration procedures, ADIZ rules, search and rescue, etc.
 - (e) GPS RAIM availability for 1 hour before to 1 hour after ETA or a time specified by the pilot.
 - (f) Other assistance as required.
- c. **Abbreviated Briefing.** Request an Abbreviated Briefing when you need information to supplement mass disseminated data, update a previous briefing, or when you need only one or two specific items. Provide the briefer with appropriate background information, the time you received the previous information, and/or the specific items needed. You should indicate the source of the information already received so that the briefer can limit the briefing to the information that you have not received, and/or appreciable changes in meteorological/aeronautical conditions since your previous briefing. To the extent possible, the briefer will provide the information in the sequence shown for a Standard Briefing. If you request only one or two specific items, the briefer will advise you if adverse conditions are present or forecast. (Adverse conditions contain both meteorological and/or aeronautical information.) Details on these conditions will be provided at your request. International data may be inaccurate or incomplete. If you are planning a flight outside of U.S. controlled airspace, the briefer will advise you to check data as soon as practical after entering foreign airspace, unless you advise that you have the international cautionary advisory.
- d. **Outlook Briefing.** You should request an Outlook Briefing whenever your proposed time of departure is six or more hours from the time of the briefing. The briefer will provide available forecast data applicable to the proposed flight. This type of briefing is provided for planning purposes only. You should obtain a Standard or Abbreviated Briefing prior to departure in order to obtain such items as adverse conditions, current conditions, updated forecasts, winds aloft and NOTAMs, etc.
- e. When filing a flight plan only, you will be asked if you require the latest information on adverse conditions pertinent to the route of flight.
- f. **Inflight Briefing.** You are encouraged to conduct a self-briefing using online resources or obtain your preflight briefing by telephone or in person (Alaska only) before departure. In those cases where you need to obtain a preflight briefing or an update to a previous briefing by radio, you should contact the nearest FSS to obtain this information. After communica-

UNITED STATES

SECTION 1. METEOROLOGY

tions have been established, advise the specialist of the type briefing you require and provide appropriate background information. You will be provided information as specified in the above paragraphs, depending on the type of briefing requested. En Route advisories tailored to the phase of flight that begins after climb-out and ends with descent to land are provided upon pilot request. Besides Flight Service, there are other resources available to the pilot in flight, including:

Automatic Dependent Surveillance-Broadcast (ADS-B). Free traffic, weather, and flight information are available on ADS-B In receivers that can receive data over 978 MHz (UAT) broadcasts. These services are available across the nation to aircraft owners who equip with ADS-B In, with further advances coming from airborne and runway traffic awareness. Even search-and-rescue operations benefit from accurate ADS-B tracking.

Flight Information Services-Broadcast (FIS-B). FIS-B is a free service; but is only available to aircraft that can receive data over 978 MHz (UAT). FIS-B automatically transmits a wide range of weather products with national and regional focus to all equipped aircraft. Having current weather and aeronautical information in the cockpit helps pilots plan more safe and efficient flight paths, as well as make strategic decisions during flight to avoid potentially hazardous weather.

Pilots are encouraged to provide a continuous exchange of information on weather, winds, turbulence, flight visibility, icing, etc., between pilots and inflight specialists. Pilots should report good weather as well as bad, and confirm expected conditions as well as unexpected. Remember that weather conditions can change rapidly and that a “go or no go” decision, as mentioned in paragraph 7-1-4b2, should be assessed at all phases of flight.

- g. Following any briefing, feel free to ask for any information that you or the briefer may have missed or are not understood. This way, the briefer is able to present the information in a logical sequence, and lessens the chance of important items being overlooked.

7-1-6 INFLIGHT AVIATION WEATHER ADVISORIES

a. Background

1. Inflight Aviation Weather Advisories are forecasts to advise en route aircraft of development of potentially hazardous weather. Inflight aviation weather advisories in the conterminous U.S. are issued by the Aviation Weather Center (AWC) in Kansas City, MO, as well as 20 Center Weather Service Units (CWSU) associated with ARTCCs. AWC also issues advisories for portions of the Gulf of Mexico, Atlantic and Pacific Oceans, which are under the control of ARTCCs with Oceanic flight information regions (FIRs). The Weather Forecast Office (WFO) in Honolulu issues advisories for the Hawaiian Islands and a large portion of the Pacific Ocean. In Alaska, the Alaska Aviation Weather Unit (AAWU) issues inflight aviation weather advisories along with the Anchorage CWSU. All heights are referenced MSL, except in the case of ceilings (CIG) which indicate AGL.
2. There are four types of inflight aviation weather advisories: the SIGMET, the Convective SIGMET, the AIRMET (text or graphical product), and the Center Weather Advisory

UNITED STATES

SECTION 1. METEOROLOGY

(CWA). All of these advisories use the same location identifiers (either VORs, airports, or well-known geographic areas) to describe the hazardous weather areas.

3. The Severe Weather Watch Bulletins (WWs), (with associated Alert Messages) (AWW) supplements these Inflight Aviation Weather Advisories.

b. SIGMET (WS)/AIRMET (WA or G-AIRMET)

SIGMETs/AIRMET text (WA) products are issued corresponding to the Area Forecast (FA) areas described in FIG 7-1-4 and FIG 7-1-5. The maximum forecast period is 4 hours for SIGMETs and 6 hours for AIRMETs. The G-AIRMET is issued over the CONUS every 6 hours, valid at 3-hour increments through 12 hours with optional forecasts possible during the first 6 hours. The first 6 hours of the G-AIRMET correspond to the 6-hour period of the AIRMET. SIGMETs and AIRMETs are considered “widespread” because they must be either affecting or be forecasted to affect an area of at least 3,000 square miles at any one time. However, if the total area to be affected during the forecast period is very large, it could be that in actuality only a small portion of this total area would be affected at any one time.

1. SIGMETs/AIRMET (or G-AIRMET) for the conterminous U.S. (CONUS)

SIGMETs/AIRMET text products for the CONUS are issued corresponding to the areas in FIG 7-1-4. The maximum forecast period for a CONUS SIGMET is 4 hours and 6 hours for CONUS AIRMETs. The G-AIRMET is issued over the CONUS every 6 hours, valid at 3-hour increments through 12 hours with optional forecasts possible during the first 6 hours. The first 6 hours of the G-AIRMET correspond to the 6-hour period of the AIRMET. SIGMETs and AIRMETs are considered “widespread” because they must be either affecting or be forecasted to affect an area of at least 3,000 square miles at any one time. However, if the total area to be affected during the forecast period is very large, it could be that in actuality only a small portion of this total area would be affected at any one time. Only SIGMETs for the CONUS are for non-convective weather. The U.S. issues a special category of SIGMETs for convective weather called Convective SIGMETs.

2. SIGMETs/AIRMETs for Alaska

Alaska SIGMETs are valid for up to 4 hours, except for Volcanic Ash Cloud SIGMETs which are valid for up to 6 hours. Alaska AIRMETs are valid for up to 8 hour.

3. SIGMETs/AIRMETs for Hawaii and U.S. FIRs in the Gulf of Mexico, Caribbean, Western Atlantic and Eastern and Central Pacific Oceans

These SIGMETs are valid for up to 4 hours, except SIGMETs for Tropical Cyclones and Volcanic Ash Clouds, which are valid for up to 6 hours. AIRMETs are issued for the Hawaiian Islands and are valid for up to 6 hours. No AIRMETs are issued for U.S. FIRs in the Gulf of Mexico, Caribbean, Western Atlantic and Pacific Oceans.

c. SIGMET

A SIGMET advises of weather that is potentially hazardous to all aircraft. SIGMETs are unscheduled products that are valid for 4 hours. However, SIGMETs associated with tropical

UNITED STATES
SECTION 1. METEOROLOGY

cyclones and volcanic ash clouds are valid for 6 hours. Unscheduled updates and corrections are issued as necessary.

1. In the CONUS, SIGMETs are issued when the following phenomena occur or are expected to occur:
 - (a) Severe icing not associated with thunderstorms.
 - (b) Severe or extreme turbulence or clear air turbulence (CAT) not associated with thunderstorms.
 - (c) Widespread dust storms or sandstorms lowering surface visibilities to below 3 miles.
 - (d) Volcanic ash.
2. In Alaska and Hawaii, SIGMETs are also issued for:
 - (a) Tornadoes.
 - (b) Lines of thunderstorms.
 - (c) Embedded thunderstorms.
 - (d) Hail greater than or equal to $\frac{3}{4}$ inch in diameter.
3. SIGMETs are identified by an alphabetic designator from November through Yankee excluding Sierra and Tango. (Sierra, Tango, and Zulu are reserved for AIRMET text [WA] products; G-AIRMETS do not use the Sierra, Tango, or Zulu designators.) The first issuance of a SIGMET will be labeled as UWS (Urgent Weather SIGMET). Subsequent issuances are at the forecaster's discretion. Issuance for the same phenomenon will be sequentially numbered, using the original designator until the phenomenon ends. For example, the first issuance in the Chicago (CHI) FA area for phenomenon moving from the Salt Lake City (SLC) FA area will be SIGMET Papa 3, if the previous two issuances, Papa 1 and Papa 2, had been in the SLC FA area. Note that no two different phenomena across the country can have the same alphabetic designator at the same time.

EXAMPLE:

Example of a SIGMET:

BOSR WS 050600

SIGMET ROMEO 2 VALID UNTIL 051000

ME NH VT

FROM CAR TO YSJ TO CON TO MPV TO CAR OCNL SEV TURB BLW 080 EXP DUE TO STG NWLY FLOW. CONDS CONTG BYD 1000Z.

d. Convective SIGMET (WST)

1. Convective SIGMETs are issued in the conterminous U.S. for any of the following:

UNITED STATES
SECTION 1. METEOROLOGY

- (a) Severe thunderstorm due to:
 - (1) Surface winds greater than or equal to 50 knots.
 - (2) Hail at the surface greater than or equal to $\frac{3}{4}$ inches in diameter.
 - (3) Tornadoes.
 - (b) Embedded thunderstorms.
 - (c) A line of thunderstorms.
 - (d) Thunderstorms producing precipitation greater than or equal to heavy precipitation affecting 40 percent or more of an area at least 3,000 square miles.
2. Any convective SIGMET implies severe or greater turbulence, severe icing, and low-level wind shear. A convective SIGMET may be issued for any convective situation that the forecaster feels is hazardous to all categories of aircraft.
3. Convective SIGMET bulletins are issued for the western (W), central (C), and eastern (E) United States. (Convective SIGMETs are not issued for Alaska or Hawaii.) The areas are separated at 87 and 107 degrees west longitude with sufficient overlap to cover most cases when the phenomenon crosses the boundaries. Bulletins are issued hourly at H+55. Special bulletins are issued at any time as required and updated at H+55. If no criteria meeting convective SIGMET requirements are observed or forecasted, the message "CONVECTIVE SIGMET... NONE" will be issued for each area at H+55. Individual convective SIGMETs for each area (W, C, E) are numbered sequentially from number one each day, beginning at 00Z. A convective SIGMET for a continuing phenomenon will be reissued every hour at H+55 with a new number. The text of the bulletin consists of either an observation and a forecast or just a forecast. The forecast is valid for up to 2 hours.

EXAMPLE: CONVECTIVE SIGMET 44C

e. SIGMET Outside the CONUS

1. Three NWS offices have been designated by ICAO as Meteorological Watch Offices (MWOs). These offices are responsible for issuing SIGMETs for designated areas outside the CONUS that include Alaska, Hawaii, portions of the Atlantic and Pacific Oceans, and the Gulf of Mexico.
2. The offices which issue international SIGMETs are:
 - (a) The AWC in Kansas City, Missouri.
 - (b) The AAWU in Anchorage, Alaska.
 - (c) The WFO in Honolulu, Hawaii.
3. SIGMETs for outside the CONUS are issued for 6 hours for volcanic ash clouds, 6 hours for tropical cyclones (e.g. hurricanes and tropical storms), and 4 hours for all other events. Like the CONUS SIGMETs, SIGMETs for outside the CONUS are also identified by an alphabetic designator from Alpha through Mike and are numbered sequentially until that weather phenomenon ends. The criteria for an international SIGMET are:
 - (a) Thunderstorms occurring in lines, embedded in clouds, or in large areas producing tornadoes or large hail.
 - (b) Tropical cyclones.
 - (c) Severe icing.
 - (d) Severe or extreme turbulence.

**UNITED STATES
SECTION 1. METEOROLOGY**

- (e) Dust storms and sandstorms lowering visibilities to less than 3 miles.
- (f) Volcanic ash.

MOSHER

f. AIRMET

1. AIRMETs (WAs) are advisories of significant weather phenomena but describe conditions at intensities lower than those which require the issuance of SIGMETs. AIRMETs are intended for dissemination to all pilots in the preflight and en route phase of flight to enhance safety. AIRMET information is available in two formats: text bulletins (WA) and graphics (G-AIRMET). Both formats meet the criteria of paragraph 7-1-3i and are issued on a scheduled basis every 6 hours beginning at 0245 UTC. Unscheduled updates and corrections are issued as necessary. AIRMETs contain details about IFR, extensive mountain obscuration, turbulence, strong surface winds, icing, and freezing levels.
2. There are three AIRMETs: Sierra, Tango, and Zulu. After the first issuance each day, scheduled or unscheduled bulletins are numbered sequentially for easier identification.
 - (a) AIRMET Sierra describes IFR conditions and/or extensive mountain obscurations.
 - (b) AIRMET Tango describes moderate turbulence, sustained surface winds of 30 knots or greater, and/or nonconvective low-level wind shear.
 - (c) AIRMET Zulu describes moderate icing and provides freezing level heights.

3. **Graphical AIRMETs (G-AIRMETs)**, found on the Aviation Weather Center webpage at <http://aviationweather.gov>, are graphical forecasts of en-route weather hazards valid at discrete times no more than 3 hours apart for a period of up to 12 hours into the future (for example, 00, 03, 06, 09, and 12 hours). Additional forecasts may be inserted during the first 6 hours (for example, 01, 02, 04, and 05). 00 hour represents the initial conditions, and the subsequent graphics depict the area affected by the particular hazard at that valid time. Forecasts valid at 00 through 06 hours correspond to the text AIRMET bulletin. Forecasts valid at 06 through 12 hours correspond to the text bulletin outlook. G-AIRMET depicts the following en route aviation weather hazards:

- (a) Instrument flight rule conditions (ceiling < 1000' and/or surface visibility <3 miles)
- (b) Mountain obscuration
- (c) Icing
- (d) Freezing level
- (e) Turbulence
- (f) Low level wind shear (LLWS)
- (g) Strong surface winds

G-AIRMETs are snap shots at discrete time intervals as defined above. The text AIRMET is the result of the production of the G-AIRMET but provided in a time smear for a 6hr valid period. G-AIRMETs provide a higher forecast resolution than text AIRMET products. Since G-AIRMETs and text AIRMETs are created from the same forecast "production" process, there exists perfect consistency between the two. Using the two together will provide clarity of the area impacted by the weather hazard and improve situational awareness and decision making.

Interpolation of time periods between G-AIRMET valid times: Users must keep in mind when using the G-AIRMET that if a 00 hour forecast shows no significant weather and a 03 hour forecast shows hazardous weather, they must assume a change is occurring during the

UNITED STATES

SECTION 1. METEOROLOGY

period between the two forecasts. It should be taken into consideration that the hazardous weather starts immediately after the 00 hour forecast unless there is a defined initiation or ending time for the hazardous weather. The same would apply after the 03 hour forecast. The user should assume the hazardous weather condition is occurring between the snap shots unless informed otherwise. For example, if a 00 hour forecast shows no hazard, a 03 hour forecast shows the presence of hazardous weather, and a 06 hour forecast shows no hazard, the user should assume the hazard exists from the 0001 hour to the 0559 hour time period.

EXAMPLE: See FIG 7-1-6 for an example of the G-AIRMET graphical product.

g. Watch Notification Messages

The Storm Prediction Center (SPC) in Norman, OK, issues Watch Notification Messages to provide an area threat alert for forecast organized severe thunderstorms that may produce tornadoes, large hail, and/or convective damaging winds within the CONUS. SPC issues three types of watch notification messages: Aviation Watch Notification Messages, Public Severe Thunderstorm Watch Notification Messages, and Public Tornado Watch Notification Messages.

It is important to note the difference between a Severe Thunderstorm (or Tornado) Watch and a Severe Thunderstorm (or Tornado) Warning. A watch means severe weather is possible during the next few hours, while a warning means that severe weather has been observed, or is expected within the hour. Only the SPC issues Severe Thunderstorm and Tornado Watches, while only NWS Weather Forecasts Offices issue Severe Thunderstorm and Tornado Warnings.

1. The Aviation Watch Notification Message. The Aviation Watch Notification Message product is an approximation of the area of the Public Severe Thunderstorm Watch or Public Tornado Watch. The area may be defined as a rectangle or parallelogram using VOR navigational aides as coordinates.

The Aviation Watch Notification Message was formerly known as the Alert Severe Weather Watch Bulletin (AWW). The NWS no longer uses that title or acronym for this product. The NWS uses the acronym SAW for the Aviation Watch Notification Message, but retains AWW in the product header for processing by weather data systems.

EXAMPLE: Example of an Aviation Watch Notification Message:

WWUS30 KWNS 271559

THIS IS AN APPROXIMATION TO THE WATCH AREA. FOR A COMPLETE DEPICTION OF THE WATCH SEE WOUS64 KWNS FOR WOU2.

2. Public Severe Thunderstorm Watch Notification Messages describe areas of expected severe thunderstorms. (Severe thunderstorm criteria are 1-inch hail or larger and/or wind gusts of 50 knots [58 mph] or greater). A Public Severe Thunderstorm Watch Notification Message contains the area description and axis, the watch expiration time, a description of hail size and thunderstorm wind gusts expected, the definition of the watch, a call to action statement, a list of other valid watches, a brief discussion of meteorological reasoning and technical information for the aviation community.
3. Public Tornado Watch Notification Messages describe areas where the threat of tornadoes exists. A Public Tornado Watch Notification Message contains the area description and axis, watch expiration time, the term "damaging tornadoes," a description of the largest hail size and strongest thunderstorm wind gusts expected, the definition of the watch, a call to action statement, a list of other valid watches, a brief discussion of meteorological reasoning and technical information for the aviation community. SPC may enhance a Public Tornado Watch Notification Message by using the words "THIS IS A PARTICULARLY DANGEROUS SITUATION" when there is a likelihood of multiple strong (damage of EF2 or EF3) or violent (damage of EF4 or EF5) tornadoes.
4. Public severe thunderstorm and tornado watch notification messages were formerly known as the Severe Weather Watch Bulletins (WW). The NWS no longer uses that title or acronym for this product but retains WW in the product header for processing by weather data systems.

EXAMPLE: Example of a Public Tornado Watch Notification Message:

WWUS20 KWNS 050550

5. Status reports are issued as needed to show progress of storms and to delineate areas no longer under the threat of severe storm activity. Cancellation bulletins are issued when it becomes evident that no severe weather will develop or that storms have subsided and are no longer severe.

h. Center Weather Advisories (CWAs)

1. CWAs are unscheduled inflight, flow control, air traffic, and air crew advisory. By nature of its short lead time, the CWA is not a flight planning product. It is generally a nowcast for conditions beginning within the next two hours. CWAs will be issued:
 - (a) As a supplement to an existing SIGMET, Convective SIGMET or AIRMET.
 - (b) When an Inflight Advisory has not been issued but observed or expected weather conditions meet SIGMET/AIRMET criteria based on current pilot reports and reinforced by other sources of information about existing meteorological conditions.

UNITED STATES

SECTION 1. METEOROLOGY

- (c) When observed or developing weather conditions do not meet SIGMET, Convective SIGMET, or AIRMET criteria; e.g., in terms of intensity or area coverage, but current pilot reports or other weather information sources indicate that existing or anticipated meteorological phenomena will adversely affect the safe flow of air traffic within the ARTCC area of responsibility.
2. The following example is a CWA issued from the Kansas City, Missouri, ARTCC. The “3” after ZKC in the first line denotes this CWA has been issued for the third weather phenomena to occur for the day. The “301” in the second line denotes the phenomena number again (3) and the issuance number (01) for this phenomena. The CWA was issued at 2140Z and is valid until 2340Z.

EXAMPLE: ZKC3 CWA 032140

ZKC CWA 301 VALID UNTIL 032340

ISOLD SVR TSTM over KCOU MOVG SWWD 10 KTS ETC.

7-1-7 CATEGORICAL OUTLOOKS

- a. Categorical outlook terms, describing general ceiling and visibility conditions for advanced planning purposes are used only in area forecasts and are defined as follows:
1. **LIFR (Low IFR).** Ceiling less than 500 feet and/or visibility less than 1 mile.
 2. **IFR.** Ceiling 500 to less than 1,000 feet and/or visibility 1 to less than 3 miles.
 3. **MVFR (Marginal VFR).** Ceiling 1,000 to 3,000 feet and/or visibility 3 to 5 miles inclusive.
 4. **VFR.** Ceiling greater than 3,000 feet and visibility greater than 5 miles; includes sky clear.
- b. The cause of LIFR, IFR, or MVFR is indicated by either ceiling or visibility restrictions or both. The contraction “CIG” and/or weather and obstruction to vision symbols are used. If winds or gusts of 25 knots or greater are forecast for the outlook period, the word “WIND” is also included for all categories including VFR.

EXAMPLE:

1. LIFR CIG—low IFR due to low ceiling.
2. IFR FG—IFR due to visibility restricted by fog.
3. MVFR CIG HZ FU—marginal VFR due to both ceiling and visibility restricted by haze and smoke.
4. IFR CIG RA WIND—IFR due to both low ceiling and visibility restricted by rain; wind expected to be 25 knots or greater.

7-1-8 INFIGHT WEATHER ADVISORY BROADCASTS

- a. ARTCCs broadcast a Convective SIGMET, SIGMET, AIRMET, Urgent Pilot Report, or CWA alert once on all frequencies, except emergency frequencies, when any part of the area

UNITED STATES
SECTION 1. METEOROLOGY

described is within 150 miles of the airspace under their jurisdiction. These broadcasts advise pilots of the availability of hazardous weather advisories and to contact the nearest Flight Service facility for additional details.

EXAMPLE:

1. Attention all aircraft, SIGMET Delta Three, from Myton to Tuba City to Milford, severe turbulence and severe clear icing below one zero thousand feet. Expected to continue beyond zero three zero zero zulu.
2. Attention all aircraft, convective SIGMET Two Seven Eastern. From the vicinity of Elmira to Phillipsburg. Scattered embedded thunderstorms moving east at one zero knots. A few intense level five cells, maximum tops four five zero.
3. Attention all aircraft, Kansas City Center weather advisory one zero three. Numerous reports of moderate to severe icing from eight to nine thousand feet in a three zero mile radius of St. Louis. Light or negative icing reported from four thousand to one two thousand feet remainder of Kansas City Center area.

NOTE: *Terminal control facilities have the option to limit hazardous weather information broadcast as follows: Tower cab and approach control positions may opt to broadcast hazardous weather information alerts only when any part of the area described is within 50 miles of the airspace under their jurisdiction.*

REFERENCE—FAA Order JO 7110.65, Para 2-6-6, Hazardous Inflight Weather Advisory.

UNITED STATES SECTION 1. METEOROLOGY

FIGURE 7-1-6
G-AIRMET Graphical Product

7-1-9 FLIGHT INFORMATION SERVICES (FIS)

FIS is a method of disseminating meteorological (MET) and aeronautical information (AI) to displays in the cockpit in order to enhance pilot situational awareness, provide decision support tools, and improve safety. FIS augments traditional pilot voice communication with Flight Service

UNITED STATES

SECTION 1. METEOROLOGY

Stations (FSSs), ATC facilities, or Airline Operations Control Centers (AOCCs). FIS is not intended to replace traditional pilot and controller/flight service specialist/aircraft dispatcher preflight briefings or inflight voice communications. FIS, however, can provide textual and graphical information that can help abbreviate and improve the usefulness of such communications. FIS enhances pilot situational awareness and improves safety.

- a. Data link Service Providers (DSPs). DSPs deploy and maintain airborne, ground-based, and, in some cases, space-based infrastructure that supports the transmission of AI/MET information over one or more physical links. A DSP may provide a free of charge or a for-fee service that permits end users to uplink and downlink AI/MET and other information. The following are examples of DSPs:
 1. FAA FIS-B. A ground-based broadcast service provided through the ADS-B Universal Access Transceiver (UAT) network. The service provides users with a 978 MHz data link capability when operating within range and line-of-sight of a transmitting ground station. FIS-B enables users of properly equipped aircraft to receive and display a suite of broadcast weather and aeronautical information products.
 2. Non-FAA FIS Systems. Several commercial vendors provide customers with FIS data over both the aeronautical spectrum and on other frequencies using a variety of data link protocols. Services available from these providers vary greatly and may include tier based subscriptions. Advancements in bandwidth technology permits preflight as well as inflight access to the same MET and AI information available on the ground. Pilots and operators using non-FAA FIS for MET and AI information should be knowledgeable regarding the weather services being provided as some commercial vendors may be repackaging NWS sourced weather, while other commercial vendors may alter the weather information to produce vendor-tailored or vendor-specific weather reports and forecasts.
- b. Three Data Link Modes. There are three data link modes that may be used for transmitting AI and MET information to aircraft. The intended use of the AI and/or MET information will determine the most appropriate data link service.
 1. Broadcast Mode: A one-way interaction in which AI and/or MET updates or changes applicable to a designated geographic area are continuously transmitted (or transmitted at repeated periodic intervals) to all aircraft capable of receiving the broadcast within the service volume defined by the system network architecture.
 2. Contract/Demand Mode: A two-way interaction in which AI and/or MET information is transmitted to an aircraft in response to a specific request.
 3. Contract/Update Mode: A two-way interaction that is an extension of the Demand Mode. Initial AI and/or MET report(s) are sent to an aircraft and subsequent updates or changes to the AI and/or MET information that meet the contract criteria are automatically or manually sent to an aircraft.
- c. To ensure airman compliance with Federal Aviation Regulations, manufacturer's operating manuals should remind airmen to contact ATC controllers, FSS specialists, operator dispatchers, or airline operations control centers for general and mission critical aviation

UNITED STATES

SECTION 1. METEOROLOGY

weather information and/or NAS status conditions (such as NOTAMs, Special Use Airspace status, and other government flight information). If FIS products are systemically modified (for example, are displayed as abbreviated plain text and/or graphical depictions), the modification process and limitations of the resultant product should be clearly described in the vendor's user guidance.

- d. Operational Use of FIS. Regardless of the type of FIS system being used, several factors must be considered when using FIS:
1. Before using FIS for inflight operations, pilots and other flight crewmembers should become familiar with the operation of the FIS system to be used, the airborne equipment to be used, including its system architecture, airborne system components, coverage service volume and other limitations of the particular system, modes of operation and indications of various system failures. Users should also be familiar with the specific content and format of the services available from the FIS provider(s). Sources of information that may provide this specific guidance include manufacturer's manuals, training programs, and reference guides.
 2. FIS should not serve as the sole source of aviation weather and other operational information. ATC, FSSs, and, if applicable, AOCC VHF/HF voice remain as a redundant method of communicating aviation weather, NOTAMs, and other operational information to aircraft in flight. FIS augments these traditional ATC/FSS/AOCC services and, for some products, offers the advantage of being displayed as graphical information. By using FIS for orientation, the usefulness of information received from conventional means may be enhanced. For example, FIS may alert the pilot to specific areas of concern that will more accurately focus requests made to FSS or AOCC for inflight updates or similar queries made to ATC.
 3. The airspace and aeronautical environment is constantly changing. These changes occur quickly and without warning. Critical operational decisions should be based on use of the most current and appropriate data available. When differences exist between FIS and information obtained by voice communication with ATC, FSS, and/or AOCC (if applicable), pilots are cautioned to use the most recent data from the most authoritative source.
 4. FIS aviation weather products (for example, graphical ground-based radar precipitation depictions) are not appropriate for tactical (typical timeframe of less than 3 minutes) avoidance of severe weather such as negotiating a path through a weather hazard area. FIS supports strategic (typical timeframe of 20 minutes or more) weather decision-making such as route selection to avoid a weather hazard area in its entirety. The misuse of information beyond its applicability may place the pilot and aircraft in jeopardy. In addition, FIS should never be used in lieu of an individual preflight weather and flight planning briefing.
 5. DSPs offer numerous MET and AI products with information that can be layered on top of each other. Pilots need to be aware that too much information can have a negative effect on their cognitive work load. Pilots need to manage the amount of information to a level that offers the most pertinent information to that specific flight without creating a

UNITED STATES

SECTION 1. METEOROLOGY

cockpit distraction. Pilots may need to adjust the amount of information based on numerous factors including, but not limited to, the phase of flight, single pilot operation, autopilot availability, class of airspace, and the weather conditions encountered.

6. FIS NOTAM products, including Temporary Flight Restriction (TFR) information, are advisory-use information and are intended for situational awareness purposes only. Cockpit displays of this information are not appropriate for tactical navigation — pilots should stay clear of any geographic area displayed as a TFR NOTAM. Pilots should contact FSSs and/or ATC while en route to obtain updated information and to verify the cockpit display of NOTAM information.
7. FIS supports better pilot decision-making by increasing situational awareness. Better decision-making is based on using information from a variety of sources. In addition to FIS, pilots should take advantage of other weather/NAS status sources, including, briefings from Flight Service Stations, data from other air traffic control facilities, airline operation control centers, pilot reports, as well as their own observations.

e. FAA's Flight Information Service-Broadcast (FIS-B).

1. FIS-B is a ground-based broadcast service provided through the FAA's Automatic Dependent Surveillance-Broadcast (ADS-B) Services Universal Access Transceiver (UAT) network. The service provides users with a 978 MHz data link capability when operating within range and line-of-sight of a transmitting ground station. FIS-B enables users of properly-equipped aircraft to receive and display a suite of broadcast weather and aeronautical information products.
2. TBL 7-1-2 lists the text and graphical products available through FIS-B and provided free-of-charge. Detailed information concerning FIS-B meteorological products can be found in Advisory Circular 00-45, Aviation Weather Services, and AC 00-63, Use of Cockpit Displays of Digital Weather and Aeronautical Information. Information on Special Use Airspace (SUA), Temporary Flight Restriction (TFR), and Notice to Air Missions (NOTAM) products can be found in Chapters 3, 4 and 5 of this manual.
3. Users of FIS-B should familiarize themselves with the operational characteristics and limitations of the system, including: system architecture; service environment; product lifecycles; modes of operation; and indications of system failure.

NOTE: *The NOTAM-D and NOTAM-FDC products broadcast via FIS-B are limited to those issued or effective within the past 30 days. Except for TFRs, NOTAMs older than 30 days are not provided. The pilot in command is responsible for reviewing all necessary information prior to flight.*

4. FIS-B products are updated and transmitted at specific intervals based primarily on product issuance criteria. Update intervals are defined as the rate at which the product data is available from the source for transmission. Transmission intervals are defined as the amount of time within which a new or updated product transmission must be completed and/or the rate or repetition interval at which the product is rebroadcast. Update and transmission intervals for each product are provided in TBL 7-1-2.

UNITED STATES
SECTION 1. METEOROLOGY

5. Where applicable, FIS-B products include a look-ahead range expressed in nautical miles (NM) for three service domains: Airport Surface; Terminal Airspace; and En Route/Gulf of Mexico (GOMEX). TBL 7-1-3 provides service domain availability and look-ahead ranging for each FIS-B product.
6. Prior to using this capability, users should familiarize themselves with the operation of FIS-B avionics by referencing the applicable User's Guides. Guidance concerning the interpretation of information displayed should be obtained from the appropriate avionics manufacturer.
7. FIS-B malfunctions not attributed to aircraft system failures or covered by active NOTAM should be reported by radio or telephone to the nearest FSS facility, or by sending an email to the ADS-B help desk at adsb@faa.gov. Reports should include:
 - (a) Condition observed;
 - (b) Date and time of observation;
 - (c) Altitude and location of observation;
 - (d) Type and call sign of the aircraft; and
 - (e) Type and software version of avionics system.
- f. Non-FAA FIS Systems. Several commercial vendors also provide customers with FIS data over both the aeronautical spectrum and on other frequencies using a variety of data link protocols. In some cases, the vendors provide only the communications system that carries customer messages, such as the Aircraft Communications Addressing and Reporting System (ACARS) used by many air carrier and other operators.
 1. Operators using non-FAA FIS data for inflight weather and other operational information should ensure that the products used conform to FAA/NWS standards. Specifically, aviation weather and NAS status information should meet the following criteria:
 - (a) The products should be either FAA/NWS "accepted" aviation weather reports or products, or based on FAA/NWS accepted aviation weather reports or products. If products are used which do not meet this criteria, they should be so identified. The operator must determine the applicability of such products to their particular flight operations.
 - (b) In the case of a weather product which is the result of the application of a process which alters the form, function or content of the base FAA/NWS accepted weather product(s), that process, and any limitations to the application of the resultant product, should be described in the vendor's user guidance material. An example would be a NEXRAD radar composite/mosaic map, which has been modified by changing the scaling resolution. The methodology of assigning reflectivity values to the resultant image components should be described in the vendor's guidance material to ensure that the user can accurately interpret the displayed data.

7-1-10 WEATHER OBSERVING PROGRAMS

- a. **Manual Observations.** With only a few exceptions, these reports are from airport locations staffed by FAA personnel who manually observe, perform calculations, and enter these observations into the (WMSCR) communication system. The format and coding of these observations are contained in paragraph 7-1-30, Key to Aviation Routine Weather Report (METAR) and Aerodrome Forecasts (TAF).
- b. **Automated Weather Observing System (AWOS).**
 1. Automated weather reporting systems are increasingly being installed at airports. These systems consist of various sensors, a processor, a computer-generated voice subsystem, and a transmitter to broadcast local, minute-by-minute weather data directly to the pilot.

UNITED STATES
SECTION 1. METEOROLOGY

NOTE: When the barometric pressure exceeds 31.00 inches Hg., see AIM, Para 7-2-3, Altimeter Errors.

2. The AWOS observations will include the prefix “AUTO” to indicate that the data are derived from an automated system. Some AWOS locations will be augmented by certified observers who will provide weather and obstruction to vision information in the remarks of the report when the reported visibility is less than 7 miles. These sites, along with the hours of augmentation, are to be published in the Chart Supplement U.S. [For telephone access to AWOS stations, refer to the Jeppesen Meteorology Section, Services and Telephone Numbers — United States and Alaska.] Augmentation is identified in the observation as “OBSERVER WEATHER.” The AWOS wind speed, direction and gusts, temperature, dew point, and altimeter setting are exactly the same as for manual observations. The AWOS will also report density altitude when it exceeds the field elevation by more than 1,000 feet. The reported visibility is derived from a sensor near the touchdown of the primary instrument runway. The visibility sensor output is converted to a visibility value using a 10-minute harmonic average. The reported sky condition/ceiling is derived from the ceilometer located next to the visibility sensor. The AWOS algorithm integrates the last 30 minutes of ceilometer data to derive cloud layers and heights. This output may also differ from the observer sky condition in that the AWOS is totally dependent upon the cloud advection over the sensor site.
3. These real-time systems are operationally classified into nine basic levels:
 - (a) **AWOS-A** only reports altimeter setting;
NOTE: Any other information is advisory only.
 - (b) **AWOS-AV** reports altimeter and visibility;
NOTE: Any other information is advisory only.
 - (c) **AWOS-1** usually reports altimeter setting, wind data, temperature, dew point, and density altitude;
 - (d) **AWOS-2** provides the information provided by AWOS-1 plus visibility; and
 - (e) **AWOS-3** provides the information provided by AWOS-2 plus cloud/ceiling data.
 - (f) **AWOS-3P** provides reports the same as the AWOS 3 system, plus a precipitation identification sensor.
 - (g) **AWOS-3PT** reports the same as the AWOS 3P System, plus thunderstorm/lightning reporting capability.
 - (h) **AWOS-3T** reports the same as AWOS 3 system and includes a thunderstorm/lightning reporting capability.
 - (i) **AWOS-4** reports the same as the AWOS 3 system, plus precipitation occurrence, type and accumulation, freezing rain, thunderstorm, and runway surface sensors.
4. The information is transmitted over a discrete VHF radio frequency or the voice portion of a local NAVAI. AWOS transmissions on a discrete VHF radio frequency are engi-

UNITED STATES
SECTION 1. METEOROLOGY

needed to be receivable to a maximum of 25 NM from the AWOS site and a maximum altitude of 10,000 feet AGL. At many locations, AWOS signals may be received on the surface of the airport, but local conditions may limit the maximum AWOS reception distance and/or altitude. The system transmits a 20 to 30 second weather message updated each minute. Pilots should monitor the designated frequency for the automated weather broadcast. A description of the broadcast is contained in subparagraph c. There is no two-way communication capability. Most AWOS sites also have a dial-up capability so that the minute-by-minute weather messages can be accessed via telephone.

5. AWOS information (system level, frequency, phone number, etc.) concerning specific locations is published, as the systems become operational, in the Chart Supplement U.S., and where applicable, on published Instrument Approach Procedures. Selected individual systems may be incorporated into nationwide data collection and dissemination networks in the future.

c. **AWOS Broadcasts.** Computer-generated voice is used in AWOS to automate the broadcast of the minute-by-minute weather observations. In addition, some systems are configured to permit the addition of an operator-generated voice message; e.g., weather remarks following the automated parameters. The phraseology used generally follows that used for other weather broadcasts. Following are explanations and examples of the exceptions.

1. **Location and Time.** The location/name and the phrase "AUTOMATED WEATHER OBSERVATION," followed by the time are announced.

- (a) If the airport's specific location is included in the airport's name, the airport's name is announced.

EXAMPLE: "Bremerton National Airport automated weather observation, one four five six zulu;"

"Ravenswood Jackson County Airport automated weather observation, one four five six zulu."

- (b) If the airport's specific location is not included in the airport's name, the location is announced followed by the airport's name.

EXAMPLE: "Sault Ste. Marie, Chippewa County International Airport automated weather observation;"

"Sandusky, Cowley Field automated weather observation."

- (c) The word "TEST" is added following "OBSERVATION" when the system is not in commissioned status.

EXAMPLE: "Bremerton National Airport automated weather observation test, one four five six zulu."

- (d) The phrase "TEMPORARILY INOPERATIVE" is added when the system is inoperative.

UNITED STATES
SECTION 1. METEOROLOGY

EXAMPLE: “Bremerton National Airport automated weather observing system temporarily inoperative.”

2. Visibility.

- (a) The lowest reportable visibility value in AWOS is “less than $\frac{1}{4}$.” It is announced as “VISIBILITY LESS THAN ONE QUARTER.”
- (b) A sensor for determining visibility is not included in some AWOS. In these systems, visibility is not announced. “VISIBILITY MISSING” is announced only if the system is configured with a visibility sensor and visibility information is not available.

3. Weather. In the future, some AWOSs are to be configured to determine the occurrence of precipitation. However, the type and intensity may not always be determined. In these systems, the word “PRECIPITATION” will be announced if precipitation is occurring, but the type and intensity are not determined.

4. Ceiling and Sky Cover.

- (a) Ceiling is announced as either “CEILING” or “INDEFINITE CEILING.” With the exception of indefinite ceilings, all automated ceiling heights are measured.

EXAMPLE: “Bremerton National Airport automated weather observation, one four five six zulu. Ceiling two thousand overcast;”

“Bremerton National Airport automated weather observation, one four five six zulu. Indefinite ceiling two hundred, sky obscured.”

- (b) The word “Clear” is not used in AWOS due to limitations in the height ranges of the sensors. No clouds detected is announced as “NO CLOUDS BELOW XXX” or, in newer systems as “CLEAR BELOW XXX” (where XXX is the range limit of the sensor).

EXAMPLE: “No clouds below one two thousand.”

“Clear below one two thousand.”

- (c) A sensor for determining ceiling and sky cover is not included in some AWOS. In these systems, ceiling and sky cover are not announced. “SKY CONDITION MISSING” is announced only if the system is configured with a ceilometer and the ceiling and sky cover information is not available.

5. Remarks. If remarks are included in the observation, the word “REMARKS” is announced following the altimeter setting.

- (a) Automated “Remarks.”
 - (1) Density Altitude.
 - (2) Variable Visibility.
 - (3) Variable Wind Direction.

UNITED STATES
SECTION 1. METEOROLOGY

(b) Manual Input Remarks. Manual input remarks are prefaced with the phrase "OBSERVER WEATHER." As a general rule the manual remarks are limited to:

- (1) Type and intensity of precipitation.
- (2) Thunderstorms and direction; and
- (3) Obstructions to vision when the visibility is 3 miles or less.

EXAMPLE: "Remarks ... density altitude, two thousand five hundred ... visibility variable between one and two ... wind direction variable between two four zero and three one zero ... observed weather ... thunderstorm moderate rain showers and fog ... thunderstorm overhead."

(c) If an automated parameter is "missing" and no manual input for that parameter is available, the parameter is announced as "MISSING." For example, a report with the dew point "missing" and no manual input available, would be announced as follows:

EXAMPLE: "Ceiling one thousand overcast ... visibility three ... precipitation ... temperature three zero, dew point missing ... wind calm ... altimeter three zero zero one."

(d) "REMARKS" are announced in the following order of priority:

- (1) Automated "REMARKS."
 - [a] Density Altitude.
 - [b] Variable Visibility.
 - [c] Variable Wind Direction.
- (2) Manual Input "REMARKS."
 - [a] Sky Condition.
 - [b] Visibility.
 - [c] Weather and Obstructions to Vision.
 - [d] Temperature.
 - [e] Dew Point.
 - [f] Wind; and
 - [g] Altimeter Setting.

EXAMPLE: "Remarks ... density altitude, two thousand five hundred ... visibility variable between one and two ... wind direction variable between two four zero and three one zero ... observer ceiling estimated two thousand broken ... observer temperature two, dew point minus five."

d. **Automated Surface Observing System (ASOS)/Automated Weather Observing System (AWOS).** The ASOS/AWOS is the primary surface weather observing system of the U.S.

UNITED STATES

SECTION 1. METEOROLOGY

(See Key to Decode an ASOS/AWOS (METAR) Observation, FIG 7-1-7 and FIG 7-1-8.) The program to install and operate these systems throughout the U.S. is a joint effort of the NWS, the FAA and the Department of Defense. ASOS/AWOS is designed to support aviation operations and weather forecast activities. The ASOS/AWOS will provide continuous minute-by-minute observations and perform the basic observing functions necessary to generate an aviation routine weather report (METAR) and other aviation weather information. The information may be transmitted over a discrete VHF radio frequency or the voice portion of a local NAVD. ASOS/AWOS transmissions on a discrete VHF radio frequency are engineered to be receivable to a maximum of 25 NM from the ASOS/AWOS site and a maximum altitude of 10,000 feet AGL. At many locations, ASOS/AWOS signals may be received on the surface of the airport, but local conditions may limit the maximum reception distance and/or altitude. While the automated system and the human may differ in their methods of data collection and interpretation, both produce an observation quite similar in form and content. For the "objective" elements such as pressure, ambient temperature, dew point temperature, wind, and precipitation accumulation, both the automated system and the observer use a fixed location and time-averaging technique. The quantitative differences between the observer and the automated observation of these elements are negligible. For the "subjective" elements, however, observers use a fixed time, spatial averaging technique to describe the visual elements (sky condition, visibility and present weather), while the automated systems use a fixed location, time averaging technique. Although this is a fundamental change, the manual and automated techniques yield remarkably similar results within the limits of their respective capabilities.

1. System Description.

- (a) The ASOS/AWOS at each airport location consists of four main components:
 - (1) Individual weather sensors.
 - (2) Data collection and processing units.
 - (3) Peripherals and displays.
- (b) The ASOS/AWOS sensors perform the basic function of data acquisition. They continuously sample and measure the ambient environment, derive raw sensor data and make them available to the collection and processing units.

2. Every ASOS/AWOS will contain the following basic set of sensors:

- (a) Cloud height indicator (one or possibly three).
- (b) Visibility sensor (one or possibly three).
- (c) Precipitation identification sensor.
- (d) Freezing rain sensor (at select sites).
- (e) Pressure sensors (two sensors at small airports; three sensors at large airports).
- (f) Ambient temperature/Dew point temperature sensor.
- (g) Anemometer (wind direction and speed sensor).

UNITED STATES
SECTION 1. METEOROLOGY

(h) Rainfall accumulation sensor.

(i) Automated Lightning Detection and Reporting System (ALDARS) (excluding Alaska and Pacific Island sites).

3. The ASOS/AWOS data outlets include:

(a) Those necessary for on-site airport users.

(b) National communications networks.

(c) Computer-generated voice (available through FAA radio broadcast to pilots, and dial-in telephone line).

NOTE: *Wind direction is reported relative to magnetic north in ATIS as well as ASOS and AWOS radio (voice) broadcasts.*

4. An ASOS/AWOS report without human intervention will contain only that weather data capable of being reported automatically. The modifier for this METAR report is "AUTO." When an observer augments or backs-up an ASOS/AWOS site, the "AUTO" modifier disappears.

5. There are two types of automated stations, AO1 for automated weather reporting stations without a precipitation discriminator, and AO2 for automated stations with a precipitation discriminator. As appropriate, "AO1" and "AO2" must appear in remarks. (A precipitation discriminator can determine the difference between liquid and frozen/freezing precipitation).

NOTE: *To decode an ASOS/AWOS report, refer to FIG 7-1-7 and FIG 7-1-8.*

REFERENCE—*A complete explanation of METAR terminology is located in AIM, Para 7-1-28, Key to Aerodrome Forecast (TAF) and Aviation Routine Weather Report (METAR).*

3- AND 6-HOUR PRECIPITATION AMOUNT: 6RRRR; precipitation amount in .01 inches for past 6 hours reported in 00, 06, 12, and 18 UTC observations and for past 3 hours in 03, 09, 15, and 21 UTC observations; a trace is 60000.	60009
24-HOUR PRECIPITATION AMOUNT: 7R24 R24 R24 R24; precipitation amount in .01 inches for past 24 hours reported in 12 UTC observation, e.g., 70015.	
HOURLY TEMPERATURE AND DEW POINT: Ts_nT_nT_nTs_nT_nT_n; tenth of degree Celsius; s_n: 1 if temperature below 0° C and 0 if temperature 0° C or higher.	T00640036
6-HOUR MAXIMUM TEMPERATURE: 1s_nT_nT_n; tenth of degree Celsius; 00, 06, 12, 18 UTC; s_n: 1 if temperature below 0° C and 0 if temperature 0° C or higher.	10066
6-HOUR MINIMUM TEMPERATURE: 2s_nT_nT_n; tenth of degree Celsius; 00, 06, 12, 18 UTC; s_n: 1 if temperature below 0° C and 0 if temperature 0° C or higher.	21012
24-HOUR MAXIMUM AND MINIMUM TEMPERATURE: 4s_nT_nT_nT_nT_nT_nT_n; tenth of degree Celsius; reported at midnight local standard time; 1 if temperature below 0° C and 0 if temperature 0° C or higher, e.g., 400461006.	
PRESSURE TENDENCY: 5app; the character (a) and change in pressure (ppp; tenths of hPa) the past 3 hours.	58033
SENSOR STATUS INDICATORS: RVRNO: RVR missing; PWINO: precipitation identifier information not available; PNO: precipitation amount not available; FZRAO: freezing rain information not available; TSNO: thunderstorm information not available; VISNO [LOC]: visibility at secondary location not available, e.g., VISNO RWY06; CHINO [LOC]: (cloud-height-indicator) sky condition at secondary location not available, e.g., CHINO RWY06.	TSNO
MAINTENANCE CHECK INDICATOR: Maintenance needed on the system.	\$
If an element or phenomena does not occur, is missing, or cannot be observed, the corresponding group and space are omitted (body and/or remarks) from that particular report, except for Sea-Level Pressure (SLPppp). SLPNO shall be reported in a METAR when the SLP is not available. U.S. DEPARTMENT OF TRANSPORTATION • FEDERAL AVIATION ADMINISTRATION • Aviation Weather Directorate, 400 7 th Street, SW, Rooms 8200-8326, Washington, D.C 20591	

- TBL 7-1-4 contains a comparison of weather observing programs and the elements reported.
- Service Standards.** During 1995, a government/industry team worked to comprehensively reassess the requirements for surface observations at the nation's airports. That work resulted in agreement on a set of service standards, and the FAA and NWS ASOS sites to which the standards would apply. The term "Service Standards" refers to the level of detail in weather observation. The service standards consist of four different levels of service (A, B, C, and D) as described below. Specific observational elements included in each service level are listed in TBL 7-1-5.
 - Service Level D** defines the minimum acceptable level of service. It is a completely automated service in which the ASOS/AWOS observation will constitute the entire observation, i.e., no additional weather information is added by a human observer. This service is referred to as a stand alone D site.

UNITED STATES
SECTION 1. METEOROLOGY

2. **Service Level C** is a service in which the human observer, usually an air traffic controller, augments or adds information to the automated observation. Service Level C also includes backup of ASOS/AWOS elements in the event of an ASOS/AWOS malfunction or an unrepresentative ASOS/AWOS report. In backup, the human observer inserts the correct or missing value for the automated ASOS/AWOS elements. This service is provided by air traffic controllers under the Limited Aviation Weather Reporting Station (LAWRS) process, FSS and NWS observers, and, at selected sites, Non-Federal Observation Program observers.

Two categories of airports require detail beyond Service Level C in order to enhance air traffic control efficiency and increase system capacity. Services at these airports are typically provided by contract weather observers, NWS observers, and, at some locations, FSS observers.

3. **Service Level B** is a service in which weather observations consist of all elements provided under Service Level C, plus augmentation of additional data beyond the capability of the ASOS/AWOS. This category of airports includes smaller hubs or special airports in other ways that have worse than average bad weather operations for thunderstorms and/or freezing/frozen precipitation, and/or that are remote airports.
4. **Service Level A**, the highest and most demanding category, includes all the data reported in Service Standard B, plus additional requirements as specified. Service Level A covers major aviation hubs and/or high volume traffic airports with average or worse weather.

TABLE 7-1-5

SERVICE LEVEL A	
Service Level A consists of all the elements of Service Levels B, C and D plus the elements listed to the right, if observed.	10 minute longline RVR at precedented sites or additional visibility increments of 1/8, 1/16 and 0 Sector visibility Variable sky condition Cloud layers above 12,000 feet and cloud types Widespread dust, sand and other obscurations Volcanic eruptions
SERVICE LEVEL B	
Service Level B consists of all the elements of Service Levels C and D plus the elements listed to the right, if observed.	Longline RVR at precedented sites (may be instantaneous readout) Freezing drizzle versus freezing rain Ice pellets Snow depth & snow increasing rapidly remarks Thunderstorm and lightning location remarks Observed significant weather not at the station remarks
SERVICE LEVEL C	
Service Level C consists of all the elements of Service Level D plus augmentation and backup by a human observer or an air traffic control specialist on location nearby. Backup consists of inserting the correct value if the system malfunctions or is unrepresentative. Augmentation consists of adding the elements listed to the right, if observed. During hours that the observing facility is closed, the site reverts to Service Level D.	Thunderstorms Tornadoes Hail Virga Volcanic ash Tower visibility Operationally significant remarks as deemed appropriate by the observer
SERVICE LEVEL D	
This level of service consists of an ASOS or AWOS continually measuring the atmosphere at a point near the runway. The ASOS or AWOS senses and measures the weather parameters listed to the right.	Wind Visibility Precipitation/Obstruction to vision Cloud height Sky cover Temperature Dew point Altimeter

7-1-11 WEATHER RADAR SERVICES

- a. The National Weather Service operates a network of radar sites for detecting coverage, intensity, and movement of precipitation. The network is supplemented by FAA and DOD radar sites in the western sections of the country. Local warning radar sites augment the network by operating on an as needed basis to support warning and forecast programs.
- b. Scheduled radar observations are taken hourly and transmitted in alpha-numeric format on weather telecommunications circuits for flight planning purposes. Under certain conditions, special radar reports are issued in addition to the hourly transmittals. Data contained in the

UNITED STATES SECTION 1. METEOROLOGY

reports are also collected by the National Center for Environmental Prediction and used to prepare national radar summary charts for dissemination on facsimile circuits.

- c. A clear radar display (no echoes) does not mean that there is no significant weather within the coverage of the radar site. Clouds and fog are not detected by the radar. However, when echoes are present, turbulence can be implied by the intensity of the precipitation, and icing is implied by the presence of the precipitation at temperatures at or below zero degrees Celsius. Used in conjunction with other weather products, radar provides invaluable information for weather avoidance and flight planning.

- d. All En Route Flight Advisory Service facilities and FSSs have equipment to directly access the radar displays from the individual weather radar sites. Specialists at these locations are trained to interpret the display for pilot briefing and inflight advisory services. The Center Weather Service Units located in ARTCCs also have access to weather radar displays and provide support to all air traffic facilities within their center's area.
- e. Additional information on weather radar products and services can be found in AC 00-45, Aviation Weather Services.

UNITED STATES
SECTION 1. METEOROLOGY

7-1-12 ATC INFLIGHT WEATHER AVOIDANCE ASSISTANCE

a. ATC Radar Weather Display.

1. ATC radars are able to display areas of precipitation by sending out a beam of radio energy that is reflected back to the radar antenna when it strikes an object or moisture which may be in the form of rain drops, hail, or snow. The larger the object is, or the more dense its reflective surface, the stronger the return will be presented. Radar weather processors indicate the intensity of reflective returns in terms of decibels (dBZ). ATC systems cannot detect the presence or absence of clouds. The ATC systems can often determine the intensity of a precipitation area, but the specific character of that area (snow, rain, hail, VIRGA, etc.) cannot be determined. For this reason, ATC refers to all weather areas displayed on ATC radar scopes as "precipitation."
2. All ATC facilities using radar weather processors with the ability to determine precipitation intensity, will describe the intensity to pilots as:
 - (a) "LIGHT" (< 26 dBZ)
 - (b) "MODERATE" (26 to 40 dBZ)
 - (c) "HEAVY" (> 40 TO 50 dBZ)
 - (d) "EXTREME" (> 50 dBZ)

NOTE: *En route ATC radar's Weather and Radar Processor (WARP) does not display light precipitation intensity.*

3. ATC facilities that, due to equipment limitations, cannot display the intensity levels of precipitation, will describe the location of the precipitation area by geographic position, or position relative to the aircraft. Since the intensity level is not available, the controller will state "INTENSITY UNKNOWN."
4. ARTCC facilities normally use a Weather and Radar Processor (WARP) to display a mosaic of data obtained from multiple NEXRAD sites. There is a time delay between actual conditions and those displayed to the controller. For example, the precipitation data on the ARTCC controller's display could be up to 6 minutes old. When the WARP is not available, a second system, the narrowband Air Route Surveillance Radar (ARSR) can display two distinct levels of precipitation intensity that will be described to pilots as "MODERATE" (30 to 40 dBZ) and "HEAVY TO EXTREME" (> 40 dBZ). The WARP processor is only used in ARTCC facilities.
5. *ATC radar is not able to detect turbulence.* Generally, turbulence can be expected to occur as the rate of rainfall or intensity of precipitation increases. Turbulence associated with greater rates of rainfall/precipitation will normally be more severe than any associated with lesser rates of rainfall/precipitation. Turbulence should be expected to occur near convective activity, even in clear air. Thunderstorms are a form of convective activity that imply severe or greater turbulence. Operation within 20 miles of thunderstorms should be approached with great caution, as the severity of turbulence can be markedly greater than the precipitation intensity might indicate.

UNITED STATES
SECTION 1. METEOROLOGY

b. Weather Avoidance Assistance.

1. To the extent possible, controllers will issue pertinent information on weather or chaff areas and assist pilots in avoiding such areas when requested. Pilots should respond to a weather advisory by either acknowledging the advisory or by acknowledging the advisory and requesting an alternative course of action as follows:
 - (a) Request to deviate off course by stating a heading or degrees, direction of deviation, and approximate number of miles. In this case, when the requested deviation is approved, navigation is at the pilot's prerogative, but must maintain the altitude assigned, and remain within the lateral restrictions issued by ATC.
 - (b) An approval for lateral deviation authorizes the pilot to maneuver left or right within the lateral limits specified in the clearance.

NOTE:

- 1. It is often necessary for ATC to restrict the amount of lateral deviation ("twenty degrees right," "up to fifteen degrees left," "up to ten degrees left or right of course").*
- 2. The term "when able, proceed direct," in an ATC weather deviation clearance, refers to the pilot's ability to remain clear of the weather when returning to course/route.*
- (c) Request a new route to avoid the affected area.
- (d) Request a change of altitude.
- (e) Request radar vectors around the affected areas.
2. For obvious reasons of safety, an IFR pilot must not deviate from the course or altitude or flight level without a proper ATC clearance. When weather conditions encountered are so severe that an immediate deviation is determined to be necessary and time will not permit approval by ATC, the pilot's emergency authority may be exercised.
3. When the pilot requests clearance for a route deviation or for an ATC radar vector, the controller must evaluate the air traffic picture in the affected area, and coordinate with other controllers (if ATC jurisdictional boundaries may be crossed) before replying to the request.
4. It should be remembered that the controller's primary function is to provide safe separation between aircraft. Any additional service, such as weather avoidance assistance, can only be provided to the extent that it does not derogate the primary function. It's also worth noting that the separation workload is generally greater than normal when weather disrupts the usual flow of traffic. ATC radar limitations and frequency congestion may also be a factor in limiting the controller's capability to provide additional service.
5. It is very important, therefore, that the request for deviation or radar vector be forwarded to ATC as far in advance as possible. Delay in submitting it may delay or even preclude ATC approval or require that additional restrictions be placed on the clearance. Insofar

UNITED STATES

SECTION 1. METEOROLOGY

as possible the following information should be furnished to ATC when requesting clearance to detour around weather activity:

- (a) Proposed point where detour will commence.
 - (b) Proposed route and extent of detour (direction and distance).
 - (c) Point where original route will be resumed.
 - (d) Flight conditions (IFR or VFR).
 - (e) Any further deviation that may become necessary as the flight progresses.
 - (f) Advise if the aircraft is equipped with functioning airborne radar.
6. To a large degree, the assistance that might be rendered by ATC will depend upon the weather information available to controllers. Due to the extremely transitory nature of severe weather situations, the controller's weather information may be of only limited value if based on weather observed on radar only. Frequent updates by pilots giving specific information as to the area affected, altitudes, intensity and nature of the severe weather can be of considerable value. Such reports are relayed by radio or phone to other pilots and controllers and also receive widespread teletypewriter dissemination.
7. Obtaining IFR clearance or an ATC radar vector to circumnavigate severe weather can often be accommodated more readily in the en route areas away from terminals because there is usually less congestion and, therefore, offer greater freedom of action. In terminal areas, the problem is more acute because of traffic density, ATC coordination requirements, complex departure and arrival routes, adjacent airports, etc. As a consequence, controllers are less likely to be able to accommodate all requests for weather detours in a terminal area or be in a position to volunteer such routing to the pilot. Nevertheless, pilots should not hesitate to advise controllers of any observed severe weather and should specifically advise controllers if they desire circumnavigation of observed weather.

7-1-13 RUNWAY VISUAL RANGE (RVR)

There are currently two configurations of RVR in the NAS commonly identified as Taskers and New Generation RVR. The Taskers are the existing configuration which uses transmissometer technology. The New Generation RVRs were deployed in November 1994 and use forward scatter technology. The New Generation RVRs are currently being deployed in the NAS to replace the existing Taskers.

- a. RVR values are measured by transmissometers mounted on 14-foot towers along the runway. A full RVR system consists of:
 1. Transmissometer projector and related items.
 2. Transmissometer receiver (detector) and related items.
 3. Analog recorder.
 4. Signal data converter and related items.

**UNITED STATES
SECTION 1. METEOROLOGY**

5. Remote digital or remote display programmer.
- b. The transmissometer projector and receiver are mounted on towers 250 feet apart. A known intensity of light is emitted from the projector and is measured by the receiver. Any obscuring matter such as rain, snow, dust, fog, haze or smoke reduces the light intensity arriving at the receiver. The resultant intensity measurement is then converted to an RVR value by the signal data converter. These values are displayed by readout equipment in the associated air traffic facility and updated approximately once every minute for controller issuance to pilots.
- c. The signal data converter receives information on the high intensity runway edge light setting in use (step 3, 4, or 5); transmission values from the transmissometer and the sensing of day or night conditions. From the three data sources, the system will compute appropriate RVR values.
- d. An RVR transmissometer established on a 250 foot baseline provides digital readouts to a minimum of 600 feet, which are displayed in 200 foot increments to 3,000 feet and in 500 foot increments from 3,000 feet to a maximum value of 6,000 feet.
- e. RVR values for Category IIIa operations extend down to 700 feet RVR; however, only 600 and 800 feet are reportable RVR increments. The 800 RVR reportable value covers a range of 701 feet to 900 feet and is therefore a valid minimum indication of Category IIIa operations.
- f. Approach categories with the corresponding minimum RVR values. (See TBL 7-1-6.)

TABLE 7-1-6 Approach Category/Minimum RVR Table

Category	Visibility (RVR)
Nonprecision	2,400 feet
Category I	1,800 feet*
Category II	1,000 feet
Category IIIa	700 feet
Category IIIb	150 feet
Category IIIc	0 feet
*1,400 feet with special equipment and authorization	

- g. Ten minute maximum and minimum RVR values for the designated RVR runway are reported in the body of the aviation weather report when the prevailing visibility is less than one mile and/or the RVR is 6,000 feet or less. ATCTs report RVR when the prevailing visibility is 1 mile or less and/or the RVR is 6,000 feet or less.
- h. Details on the requirements for the operational use of RVR are contained in FAA AC 97-1, Runway Visual Range (RVR). Pilots are responsible for compliance with minimums prescribed for their class of operations in the appropriate CFRs and/or operations specifications.

UNITED STATES

SECTION 1. METEOROLOGY

- i. RVR values are also measured by forward scatter meters mounted on 14-foot frangible fiberglass poles. A full RVR system consists of:
 1. Forward scatter meter with a transmitter, receiver and associated items.
 2. A runway light intensity monitor (RLIM).
 3. An ambient light sensor (ALS).
 4. A data processor unit (DPU).
 5. Controller display (CD).
- j. The forward scatter meter is mounted on a 14-foot frangible pole. Infrared light is emitted from the transmitter and received by the receiver. Any obscuring matter such as rain, snow, dust, fog, haze or smoke increases the amount of scattered light reaching the receiver. The resulting measurement along with inputs from the runway light intensity monitor and the ambient light sensor are forwarded to the DPU which calculates the proper RVR value. The RVR values are displayed locally and remotely on controller displays.
- k. The runway light intensity monitors both the runway edge and centerline light step settings (steps 1 through 5). Centerline light step settings are used for CAT IIIb operations. Edge Light step settings are used for CAT I, II, and IIIa operations.
- l. New Generation RVRs can measure and display RVR values down to the lowest limits of Category IIIb operations (150 feet RVR). RVR values are displayed in 100 feet increments and are reported as follows:
 1. 100-feet increments for products below 800 feet.
 2. 200-feet increments for products between 800 feet and 3,000 feet.
 3. 500-feet increments for products between 3,000 feet and 6,500 feet.
 4. 25-meter increments for products below 150 meters.
 5. 50-meter increments for products between 150 meters and 800 meters.
 6. 100-meter increments for products between 800 meters and 1,200 meters.
 7. 200-meter increments for products between 1,200 meters and 2,000 meters.

7-1-14 REPORTING OF CLOUD HEIGHTS

- a. Ceiling, by definition in the CFRs and as used in aviation weather reports and forecasts, is the height above ground (or water) level of the lowest layer of clouds or obscuring phenomenon that is reported as “broken,” “overcast,” or “obscuration,” e.g., an aerodrome forecast (TAF) which reads “BKN030” refers to height above ground level. An area forecast which reads “BKN030” indicates that the height is above mean sea level.

REFERENCE—AIM, Paragraph 7-1-28, Key to Aerodrome Forecast (TAF) and Aviation Routine Weather Report (METAR), defines “broken,” “overcast,” and “obscuration.”

- b. Pilots usually report height values above MSL, since they determine heights by the altimeter. This is taken in account when disseminating and otherwise applying information received

UNITED STATES

SECTION 1. METEOROLOGY

from pilots. ("Ceiling" heights are always above ground level.) In reports disseminated as PIREPs, height references are given the same as received from pilots, that is, above MSL.

- c. In area forecasts or inflight advisories, ceilings are denoted by the contraction "CIG" when used with sky cover symbols as in "LWRG TO CIG OVC005," or the contraction "AGL" after, the forecast cloud height value. When the cloud base is given in height above MSL, it is so indicated by the contraction "MSL" or "ASL" following the height value. The heights of clouds tops, freezing level, icing, and turbulence are always given in heights above ASL or MSL.

7-1-15 REPORTING PREVAILING VISIBILITY

- a. Surface (horizontal) visibility is reported in METAR reports in terms of statute miles and increments thereof; e.g., $\frac{1}{16}$, $\frac{1}{8}$, $\frac{3}{16}$, $\frac{1}{4}$, $\frac{5}{16}$, $\frac{3}{8}$, $\frac{1}{2}$, $\frac{5}{8}$, $\frac{3}{4}$, $\frac{7}{8}$, 1, $1\frac{1}{8}$, etc. (Visibility reported by an unaugmented automated site is reported differently than in a manual report, i.e., ASOS/AWOS: 0, $\frac{1}{16}$, $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, 1, $1\frac{1}{4}$, $1\frac{1}{2}$, $1\frac{3}{4}$, 2, $2\frac{1}{2}$, 3, 4, 5, etc., AWOS: $M\frac{1}{4}$, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, 1, $1\frac{1}{4}$, $1\frac{1}{2}$, $1\frac{3}{4}$, 2, $2\frac{1}{2}$, 3, 4, 5, etc.) Visibility is determined through the ability to see and identify preselected and prominent objects at a known distance from the usual point of observation. Visibilities which are determined to be less than 7 miles, identify the obscuring atmospheric condition; e.g., fog, haze, smoke, etc., or combinations thereof.
- b. Prevailing visibility is the greatest visibility equaled or exceeded throughout at least one half of the horizon circle, not necessarily contiguous. Segments of the horizon circle which may have a significantly different visibility may be reported in the remarks section of the weather report; i.e., the southeastern quadrant of the horizon circle may be determined to be 2 miles in mist while the remaining quadrants are determined to be 3 miles in mist.
- c. When the prevailing visibility at the usual point of observation, or at the tower level, is less than 4 miles, certificated tower personnel will take visibility observations in addition to those taken at the usual point of observation. The lower of these two values will be used as the prevailing visibility for aircraft operations.

7-1-16 ESTIMATING INTENSITY OF RAIN AND ICE PELLETS

a. Rain

- 1. **Light.** From scattered drops that, regardless of duration, do not completely wet an exposed surface up to a condition where individual drops are easily seen.
- 2. **Moderate.** Individual drops are not clearly identifiable; spray is observable just above pavements and other hard surfaces.
- 3. **Heavy.** Rain seemingly falls in sheets; individual drops are not identifiable; heavy spray to height of several inches is observed over hard surfaces.

b. Ice Pellets

- 1. **Light.** Scattered pellets that do not completely cover an exposed surface regardless of duration. Visibility is not affected.

UNITED STATES
SECTION 1. METEOROLOGY

2. **Moderate.** Slow accumulation on ground. Visibility reduced by ice pellets to less than 7 statute miles.
3. **Heavy.** Rapid accumulation on ground. Visibility reduced by ice pellets to less than 3 statute miles.

7-1-17 ESTIMATING INTENSITY OF SNOW OR DRIZZLE (BASED ON VISIBILITY)

- a. **Light.** Visibility more than $\frac{1}{2}$ statute mile.
- b. **Moderate.** Visibility from more than $\frac{1}{4}$ statute mile to $\frac{1}{2}$ statute mile.
- c. **Heavy.** Visibility $\frac{1}{4}$ statute mile or less.

7-1-18 PILOT WEATHER REPORTS (PIREPs)

- a. FAA air traffic facilities are required to solicit PIREPs when the following conditions are reported or forecast: ceilings at or below 5,000 feet; visibility at or below 5 miles (surface or aloft); thunderstorms and related phenomena; icing of light degree or greater; turbulence of moderate degree or greater; wind shear and reported or forecast volcanic ash clouds.
- b. Pilots are urged to cooperate and promptly volunteer reports of these conditions and other atmospheric data such as: cloud bases, tops and layers; flight visibility; precipitation; visibility restrictions such as haze, smoke and dust; wind at altitude; and temperature aloft.
- c. PIREPs should be given to the ground facility with which communications are established; i.e., FSS, ARTCC, or terminal ATC. One of the primary duties of the inflight position is to serve as a collection point for the exchange of PIREPs with en route aircraft.
- d. If pilots are not able to make PIREPs by radio, reporting upon landing of the inflight conditions encountered to the nearest FSS or Weather Forecast Office will be helpful. Some of the uses made of the reports are:
 1. The ATCT uses the reports to expedite the flow of air traffic in the vicinity of the field and for hazardous weather avoidance procedures.
 2. The FSS uses the reports to brief other pilots, to provide inflight advisories, and weather avoidance information to en route aircraft.
 3. The ARTCC uses the reports to expedite the flow of en route traffic, to determine most favorable altitudes, and to issue hazardous weather information within the center's area.
 4. The NWS uses the reports to verify or amend conditions contained in aviation forecast and advisories. In some cases, pilot reports of hazardous conditions are the triggering mechanism for the issuance of advisories. They also use the reports for pilot weather briefings.
 5. The NWS, other government organizations, the military, and private industry groups use PIREPs for research activities in the study of meteorological phenomena.

UNITED STATES

SECTION 1. METEOROLOGY

6. All air traffic facilities and the NWS forward the reports received from pilots into the weather distribution system to assure the information is made available to all pilots and other interested parties.
- e. The FAA, NWS, and other organizations that enter PIREPs into the weather reporting system use the format listed in TBL 7-1-7. Items 1 through 6 are included in all transmitted PIREPs along with one or more of items 7 through 13. Although the PIREP should be as complete and concise as possible, pilots should not be overly concerned with strict format or phraseology. The important thing is that the information is relayed so other pilots may benefit from your observation. If a portion of the report needs clarification, the ground station will request the information. Completed PIREPs will be transmitted to weather circuits as in the following examples:

EXAMPLE:

1. KCMH UA /OV APE 230010/TM 1516/FL085/TP BE20/SK BKN065/WX FV03SM HZ FU/TA 20/TB LGT

NOTE:

1. *One zero miles southwest of Appleton VOR; time 1516 UTC; altitude eight thousand five hundred; aircraft type BE200; bases of the broken cloud layer is six thousand five hundred; flight visibility 3 miles with haze and smoke; air temperature 20 degrees Celsius; light turbulence.*

EXAMPLE:

2. KCRW UV /OV KBKW 360015—KCRW/TM 1815/FL120//TP BE99/SK IMC/WX RA/TA M08 /WV 290030/TB LGT—MDT/IC LGT RIME/RM MDT MXD ICG DURC KROA NWBND FL080—100 1750Z

NOTE:

2. *From 15 miles north of Beckley VOR to Charleston VOR; time 1815 UTC; altitude 12,000 feet; type aircraft, BE-99; in clouds; rain; temperature minus 8 Celsius; wind 290 degrees magnetic at 30 knots; light to moderate turbulence; light rime icing during climb northwestbound from Roanoke, VA, between 8,000 and 10,000 feet at 1750 UTC.*

- f. For more detailed information on PIREPS, users can refer to the current version of AC 00-45, Aviation Weather Services.

12.	Icing	/IC	See AIM paragraph 7-1-19
13.	Remarks	/RM	For reporting elements not included or to clarify previously reported items

7-1-19 PIREPs RELATING TO AIRFRAME ICING

- a. The effects of ice on aircraft are cumulative- thrust is reduced, drag increases, lift lessens, and weight increases. The results are an increase in stall speed and a deterioration of aircraft performance. In extreme cases, 2 to 3 inches of ice can form on the leading edge of the airfoil in less than 5 minutes. It takes but $\frac{1}{2}$ inch of ice to reduce the lifting power of some aircraft by 50 percent and increases the frictional drag by an equal percentage.
- b. A pilot can expect icing when flying in visible precipitation, such as rain or cloud droplets, and the temperature is between +02 and -10 degrees Celsius. When icing is detected, a pilot should do one of two things, particularly if the aircraft is not equipped with deicing equipment; get out of the area of precipitation; or go to an altitude where the temperature is above freezing. This "warmer" altitude may not always be a lower altitude. Proper preflight action includes obtaining information on the freezing level and the above freezing levels in precipitation areas. Report icing to ATC, and if operating IFR, request new routing or altitude if icing will be a hazard. Be sure to give the type of aircraft to ATC when reporting icing. The following describes how to report icing conditions.

1. **Trace.** Ice becomes noticeable. The rate of accumulation is slightly greater than the rate of sublimation. A representative accretion rate for reference purposes is less than

UNITED STATES

SECTION 1. METEOROLOGY

¼ inch (6 mm) per hour on the outer wing. The pilot should consider exiting the icing conditions before they become worse.

2. **Light.** The rate of ice accumulation requires occasional cycling of manual deicing systems to minimize ice accretions on the airframe. A representative accretion rate for reference purposes is ¼ inch to 1 inch (0.6 to 2.5 cm) per hour on the unprotected part of the outer wing. The pilot should consider exiting the icing condition.
3. **Moderate.** The rate of ice accumulation requires frequent cycling of manual deicing systems to minimize ice accretions on the airframe. A representative accretion rate for reference purposes is 1 to 3 inches (2.5 to 7.5 cm) per hour on the unprotected part of the outer wing. The pilot should consider exiting the icing condition as soon as possible.
4. **Severe.** The rate of ice accumulation is such that ice protection systems fail to remove the accumulation of ice and ice accumulates in locations not normally prone to icing, such as areas aft of protected surfaces and any other areas identified by the manufacturer. A representative accretion rate for reference purposes is more than 3 inches (7.5 cm) per hour on the unprotected part of the outer wing. By regulation, immediate exit is required.

NOTE: *Severe icing is aircraft dependent, as are the other categories of icing intensity. Severe icing may occur at any ice accumulation rate when the icing rate or ice accumulations exceed the tolerance of the aircraft.*

EXAMPLE: Pilot report: give aircraft identification, location, time (UTC), intensity of type, altitude/FL, aircraft type, indicated air speed (IAS), and outside air temperature (OAT).

NOTE:

1. *Rime ice. Rough, milky, opaque ice formed by the instantaneous freezing of small supercooled water droplets.*
2. *Clear ice. A glossy, clear, or translucent ice formed by the relatively slow freezing of large supercooled water droplets.*
3. *The OAT should be requested by the FSS or ATC if not included in the PIREP.*

7-1-20 DEFINITIONS OF INFLIGHT ICING TERMS

See TBL 7-1-8, Icing Types, and TBL 7-1-9, Icing Conditions.

**UNITED STATES
SECTION 1. METEOROLOGY**

TABLE 7-1-8 Icing Types

Clear Ice	See Glaze Ice.
Glaze Ice	Ice, sometimes clear and smooth, but usually containing some air pockets, which results in a lumpy translucent appearance. Glaze ice results from supercooled drops/droplets striking a surface but not freezing rapidly on contact. Glaze ice is denser, harder, and sometimes more transparent than rime ice. Factors, which favor glaze formation, are those that favor slow dissipation of the heat of fusion (i.e., slight supercooling and rapid accretion). With larger accretions, the ice shape typically includes “horns” protruding from unprotected leading edge surfaces. It is the ice shape, rather than the clarity or color of the ice, which is most likely to be accurately assessed from the cockpit. The terms “clear” and “glaze” have been used for essentially the same type of ice accretion, although some reserve “clear” for thinner accretions which lack horns and conform to the airfoil.
Intercycle Ice	Ice which accumulates on a protected surface between actuation cycles of a deicing system.
Known or Observed or Detected Ice Accretion	Actual ice observed visually to be on the aircraft by the flight crew or identified by on-board sensors.
Mixed Ice	Simultaneous appearance or a combination of rime and glaze ice characteristics. Since the clarity, color, and shape of the ice will be a mixture of rime and glaze characteristics, accurate identification of mixed ice from the cockpit may be difficult.
Residual Ice	Ice which remains on a protected surface immediately after the actuation of a deicing system.
Rime Ice	A rough, milky, opaque ice formed by the rapid freezing of supercooled drops/droplets after they strike the aircraft. The rapid freezing results in air being trapped, giving the ice its opaque appearance and making it porous and brittle. Rime ice typically accretes along the stagnation line of an airfoil and is more regular in shape and conformal to the airfoil than glaze ice. It is the ice shape, rather than the clarity or color of the ice, which is most likely to be accurately assessed from the cockpit.
Runback Ice	Ice which forms from the freezing or refreezing of water leaving protected surfaces and running back to unprotected surfaces.

NOTE: Ice types are difficult for the pilot to discern and have uncertain effects on an airplane in flight. Ice type definitions will be included in the AIM for use in the “Remarks” section of the PIREP and for use in forecasting.

**UNITED STATES
SECTION 1. METEOROLOGY**

TABLE 7-1-9 Icing Conditions

Appendix C Icing Conditions	Appendix C (14 CFR, Part 25 and 29) is the certification icing condition standard for approving ice protection provisions on aircraft. The conditions are specified in terms of altitude, temperature, liquid water content (LWC), representative droplet size (mean effective drop diameter [MED]), and cloud horizontal extent.
Forecast Icing Conditions	Environmental conditions expected by a National Weather Service or an FAA-approved weather provider to be conducive to the formation of inflight icing on aircraft.
Freezing Drizzle (FZDZ)	Drizzle is precipitation at ground level or aloft in the form of liquid water drops which have diameters less than 0.5 mm and greater than 0.05 mm. Freezing drizzle is drizzle that exists at air temperatures less than 0°C (supercooled), remains in liquid form, and freezes upon contact with objects on the surface or airborne.
Freezing Precipitation	Freezing precipitation is freezing rain or freezing drizzle falling through or outside of visible cloud.
Freezing Rain (FZRA)	Rain is precipitation at ground level or aloft in the form of liquid water drops which have diameters greater than 0.5 mm. Freezing rain is rain that exists at air temperatures less than 0°C (supercooled), remains in liquid form, and freezes upon contact with objects on the ground or in the air.
Icing in Cloud	Icing occurring within visible cloud. Cloud droplets (diameter < 0.05 mm) will be present; freezing drizzle and/or freezing rain may or may not be present.
Icing in Precipitation	Icing occurring from an encounter with freezing precipitation, that is, supercooled drops with diameters exceeding 0.05 mm, within or outside of visible cloud.
Known Icing Conditions	Atmospheric conditions in which the formation of ice is observed or detected in flight. NOTE: <i>Because of the variability in space and time of atmospheric conditions, the existence of a report of observed icing does not assure the presence or intensity of icing conditions at a later time, nor can a report of no icing assure the absence of icing conditions at a later time.</i>
Potential Icing Conditions	Atmospheric icing conditions that are typically defined by airframe manufacturers relative to temperature and visible moisture that may result in aircraft ice accretion on the ground or in flight. The potential icing conditions are typically defined in the Airplane Flight Manual or in the Airplane Operation Manual.

**UNITED STATES
SECTION 1. METEOROLOGY**

TABLE 7-1-9 Icing Conditions (continued)

Supercooled Drizzle Drops (SCDD)	Synonymous with freezing drizzle aloft.
Supercooled Drops or / Droplets	Water drops/droplets which remain unfrozen at temperatures below 0°C. Supercooled drops are found in clouds, freezing drizzle, and freezing rain in the atmosphere. These drops may impinge and freeze after contact on aircraft surfaces.
Supercooled Large Drops (SLD)	Liquid droplets with diameters greater than 0.05 mm at temperatures less than 0°C, i.e., freezing rain or freezing drizzle.

7-1-21 PIREPs RELATING TO TURBULENCE

- a. When encountering turbulence, pilots are urgently requested to report such conditions to ATC as soon as practicable. PIREPs relating to turbulence should state:
 1. **Aircraft location.**
 2. **Time of occurrence in UTC.**
 3. **Turbulence intensity.**
 4. **Whether the turbulence occurred in or near clouds.**
 5. **Aircraft altitude or flight level.**
 6. **Type of aircraft.**
 7. **Duration of turbulence.**

EXAMPLE:

1. Over Omaha, 1232Z, moderate turbulence in clouds at Flight Level three one zero, Boeing 707.
2. From five zero miles south of Albuquerque to three zero miles north of Phoenix, 1250Z, occasional moderate chop at Flight Level three three zero, DC8.

- b. Duration and classification of intensity should be made using TBL 7-1-10.

UNITED STATES
SECTION 1. METEOROLOGY

TABLE 7-1-10 Turbulence Reporting Criteria Table

Intensity	Aircraft Reaction	Reaction Inside Aircraft	Reporting Term-Definition
Light	Turbulence that momentarily causes slight, erratic changes in altitude and/or attitude (pitch, roll, yaw). Report as Light Turbulence ; ¹	Occupants may feel a slight strain against seat belts or shoulder straps. Unsecured objects may be displaced slightly. Food service may be conducted and little or no difficulty is encountered in walking.	Occasional — Less than $\frac{1}{3}$ of the time.
	or		Intermittent — $\frac{1}{3}$ to $\frac{2}{3}$.
	Turbulence that causes slight, rapid and somewhat rhythmic bumpiness without appreciable changes in altitude or attitude. Report as Light Chop . ¹		Continuous — More than $\frac{2}{3}$.
Moderate	Turbulence that is similar to Light Turbulence but of greater intensity. Changes in altitude and/or attitude occur but the aircraft remains in positive control at all times. It usually causes variations in indicated air-speed. Report as Moderate Turbulence;¹ or Turbulence that is similar to Light Chop but of greater intensity. It causes rapid bumps or jolts without appreciable changes in aircraft altitude or attitude. Report as Moderate Chop.¹	Occupants feel definite strains against seat belts or shoulder straps. Unsecured objects are dislodged. Food service and walking are difficult.	NOTE: <i>Pilots should report location(s), time (UTC), intensity, whether in or near clouds, altitude, type of aircraft and, when applicable, duration of turbulence.</i> <i>Duration may be based on time between two locations or over a single location. All locations should be readily identifiable.</i>

UNITED STATES SECTION 1. METEOROLOGY

TABLE 7-1-10 Turbulence Reporting Criteria Table (continued)

Intensity	Aircraft Reaction	Reaction Inside Aircraft	Reporting Term-Definition
Severe	Turbulence that causes large, abrupt changes in altitude and/or attitude. It usually causes large variations in indicated airspeed. Aircraft may be momentarily out of control. Report as Severe Turbulence . ¹	Occupants are forced violently against seat belts or shoulder straps. Unsecured objects are tossed about. Food Service and walking are impossible.	EXAMPLE: a. Over Omaha. 1232Z, Moderate Turbulence, in cloud, Flight Level 310, B707.
Extreme	Turbulence in which the aircraft is violently tossed about and is practically impossible to control. It may cause structural damage. Report as Extreme Turbulence . ¹		b. From 50 miles south of Albuquerque to 30 miles north of Phoenix, 1210Z to 1250Z, occasional Moderate Chop, Flight Level 330, DC8.

¹ High level turbulence (normally above 15,000 feet ASL) not associated with cumuliform cloudiness, including thunderstorms, should be reported as CAT (clear air turbulence) preceded by the appropriate intensity, or light or moderate chop.

7-1-22 WIND SHEAR PIREPs

- a. Because unexpected changes in wind speed and direction can be hazardous to aircraft operations at low altitudes on approach to and departing from airports, pilots are urged to promptly volunteer reports to controllers of wind shear conditions they encounter. An advance warning of this information will assist other pilots in avoiding or coping with a wind shear on approach or departure.
- b. When describing conditions, use of the terms "negative" or "positive" wind shear should be avoided. PIREPs of "negative wind shear on final," intended to describe loss of airspeed and lift, have been interpreted to mean that no wind shear was encountered. The recommended method for wind shear reporting is to state the loss or gain of airspeed and the altitudes at which it was encountered.

EXAMPLE:

1. Denver Tower, Cessna 1234 encountered wind shear, loss of 20 knots at 400.
2. Tulsa Tower, American 721 encountered wind shear on final, gained 25 knots between 600 and 400 feet followed by loss of 40 knots between 400 feet and surface.
1. Pilots who are not able to report wind shear in these specific terms are encouraged to make reports in terms of the effect upon their aircraft.

UNITED STATES

SECTION 1. METEOROLOGY

EXAMPLE: Miami Tower, Gulfstream 403 Charlie encountered an abrupt wind shear at 800 feet on final, max thrust required.

2. Pilots using Inertial Navigation Systems (INSs) should report the wind and altitude both above and below the shear level.

c. Wind Shear Escape

1. Pilots should report to ATC when they are performing a wind shear escape maneuver. This report should be made as soon as practicable, but not until aircraft safety and control is assured, which may not be satisfied until the aircraft is clear of the wind shear or microburst. ATC should provide safety alerts and traffic advisories, as appropriate.

EXAMPLE: “Denver Tower, United 1154, wind shear escape.”

2. Once the pilot initiates a wind shear escape maneuver, ATC is not responsible for providing approved separation between the aircraft and any other aircraft, airspace, terrain, or obstacle until the pilot reports that the escape procedure is complete and approved separation has been re-established. Pilots should advise ATC that they are resuming the previously assigned clearance or should request an alternate clearance.

EXAMPLE: “Denver Tower, United 1154, wind shear escape complete, resuming last assigned heading/(name) DP/clearance.”

or

“Denver Tower, United 1154, wind shear escape complete, request further instructions.”

7-1-23 CLEAR AIR TURBULENCE (CAT) PIREPs

CAT has become a very serious operational factor to flight operations at all levels and especially to jet traffic flying in excess of 15,000 feet. The best available information on this phenomenon must come from pilots via the PIREP reporting procedures. All pilots encountering CAT conditions are urgently requested to report time, location, and intensity (light, moderate, severe, or extreme) of the element to the FAA facility with which they are maintaining radio contact. If time and conditions permit, elements should be reported according to the standards for other PIREPs and position reports.

REFERENCE—AIM, Para 7-1-21, *PIREPs Relating to Turbulence*.

7-1-24 MICROBURSTS

- a. Relatively recent meteorological studies have confirmed the existence of microburst phenomenon. Microbursts are small scale intense downdrafts which, on reaching the surface, spread outward in all directions from the downdraft center. This causes the presence of both vertical and horizontal wind shears that can be extremely hazardous to all types and categories of aircraft, especially at low altitudes. Due to their small size, short life span, and the fact that they can occur over areas without surface precipitation, microbursts are not easily detectable using conventional weather radar or wind shear alert systems.
- b. Parent clouds producing microburst activity can be any of the low or middle layer convective cloud types. Note, however, that microbursts commonly occur within the heavy rain portion

UNITED STATES

SECTION 1. METEOROLOGY

of thunderstorms, and in much weaker, benign appearing convective cells that have little or no precipitation reaching the ground.

- c. The life cycle of a microburst as it descends in a convective rain shaft is seen in FIG 7-1-12. An important consideration for pilots is the fact that the microburst intensifies for about 5 minutes after it strikes the ground.

Vertical cross section of the evolution of a microburst wind field. T is the time of initial divergence at the surface. The shading refers to the vector wind speeds. Figure adapted from Wilson et al., 1984, Microburst Wind Structure and Evaluation of Doppler Radar for Wind Shear Detection, DOT/FAA Report No. DOT/FAA/PM-84/29, National Technical Information Service, Springfield, VA 37 pp.

d. **Characteristics of microbursts include:**

1. **Size.** The microburst downdraft is typically less than 1 mile in diameter as it descends from the cloud base to about 1,000-3,000 feet above the ground. In the transition zone near the ground, the downdraft changes to a horizontal outflow that can extend to approximately $2\frac{1}{2}$ miles in diameter.
2. **Intensity.** The downdrafts can be as strong as 6,000 feet per minute. Horizontal winds near the surface can be as strong as 45 knots resulting in a 90 knot shear (headwind to tailwind change for a traversing aircraft) across the microburst. These strong horizontal winds occur within a few hundred feet of the ground.
3. **Visual Signs.** Microbursts can be found almost anywhere that there is convective activity. They may be embedded in heavy rain associated with a thunderstorm or in light rain in benign appearing virga. When there is little or no precipitation at the surface accom-

UNITED STATES

SECTION 1. METEOROLOGY

panying the microburst, a ring of blowing dust may be the only visual clue of its existence.

4. **Duration.** An individual microburst will seldom last longer than 15 minutes from the time it strikes the ground until dissipation. The horizontal winds continue to increase during the first 5 minutes with the maximum intensity winds lasting approximately 2-4 minutes. Sometimes microbursts are concentrated into a line structure, and under these conditions, activity may continue for as long as an hour. Once microburst activity starts, multiple microbursts in the same general area are not uncommon and should be expected.

FIGURE 7-1-13

Microburst Encounter During Takeoff

A microburst encounter during takeoff. The airplane first encounters a headwind and experiences increasing performance (1), this is followed in short succession by a decreasing headwind component (2), a downdraft (3), and finally a strong tailwind (4), where 2 through 5 all result in decreasing performance of the airplane. Position (5) represents an extreme situation just prior to impact. Figure courtesy of Walter Frost, FWG Associates, Inc., Tullahoma, Tennessee.

- e. Microburst wind shear may create a severe hazard for aircraft within 1,000 feet of the ground, particularly during the approach to landing and landing and take-off phases. The impact of a microburst on aircraft which have the unfortunate experience of penetrating one is characterized in FIG 7-1-13. The aircraft may encounter a headwind (performance

UNITED STATES SECTION 1. METEOROLOGY

increasing) followed by a downdraft and tailwind (both performance decreasing), possibly resulting in terrain impact.

FIGURE 7-1-14
NAS Wind Shear Product Systems

f. Detection of Microbursts, Wind Shear and Gust Fronts.

1. FAA's Integrated Wind Shear Detection Plan.

- The FAA currently employs an integrated plan for wind shear detection that will significantly improve both the safety and capacity of the majority of the airports currently served by the air carriers. This plan integrates several programs, such as the Integrated Terminal Weather System (ITWS), Terminal Doppler Weather Radar (TDWR), Weather Systems Processor (WSP), and Low Level Wind Shear Alert

UNITED STATES

SECTION 1. METEOROLOGY

Systems (LLWAS) into a single strategic concept that significantly improves the aviation weather information in the terminal area. (See FIG 7-1-14.)

- (b) The wind shear/microburst information and warnings are displayed on the ribbon display terminals (RBDT) located in the tower cabs. They are identical (and standardized) in the LLWAS, TDWR and WSP systems, and so designed that the controller does not need to interpret the data, but simply read the displayed information to the pilot. The RBDTs are constantly monitored by the controller to ensure the rapid and timely dissemination of any hazardous event(s) to the pilot.
- (c) The early detection of a wind shear/micro-burst event, and the subsequent warning(s) issued to an aircraft on approach or departure, will alert the pilot/crew to the potential of, and to be prepared for, a situation that could become very dangerous! Without these warnings, the aircraft may NOT be able to climb out of, or safely transition, the event, resulting in a catastrophe. The air carriers, working with the FAA, have developed specialized training programs using their simulators to train and prepare their pilots on the demanding aircraft procedures required to escape these very dangerous wind shear and/or microburst encounters.

2. Low Level Wind Shear Alert System (LLWAS).

- (a) The LLWAS provides wind data and software processes to detect the presence of hazardous wind shear and microbursts in the vicinity of an airport. Wind sensors, mounted on poles sometimes as high as 150 feet, are (ideally) located 2,000 – 3,500 feet, but not more than 5,000 feet, from the centerline of the runway. (See FIG 7-1-15.)

UNITED STATES
SECTION 1. METEOROLOGY

FIGURE 7-1-15
LLWAS Siting Criteria

- (b) LLWAS was fielded in 1988 at 110 airports across the nation. Many of these systems have been replaced by new TDWR and WSP technology. While all legacy LLWAS systems will eventually be phased out, 39 airports will be upgraded to LLWAS-NE (Network Expansion) system. The new LLWAS-NE systems not only provide the controller with wind shear warnings and alerts, including wind shear/microburst detection at the airport wind sensor location, but also provide the location of the hazards relative to the airport runway(s). It also has the flexibility and capability to grow with the airport as new runways are built. As many as 32 sensors, strategically located around the airport and in relationship to its runway configuration, can be accommodated by the LLWAS-NE network.

UNITED STATES
SECTION 1. METEOROLOGY

FIGURE 7-1-16

Warning Boxes

3. Terminal Doppler Weather Radar (TDWR).

- (a) TDWRs have been deployed at 45 locations across the U.S. Optimum locations for TDWRs are 8 to 12 miles off of the airport proper, and designed to look at the air-space around and over the airport to detect microbursts, gust fronts, wind shifts and precipitation intensities. TDWR products advise the controller of wind shear and microburst events impacting all runways and the areas $\frac{1}{2}$ mile on either side of the extended centerline of the runways out to 3 miles on final approach and 2 miles out on departure. (FIG 7-1-16 is a theoretical view of the warning boxes, including the runway, that the software uses in determining the location(s) of wind shear or microbursts). These warnings are displayed (as depicted in the examples in subparagraph 5) on the RBDT.
- (b) It is very important to understand what TDWR does NOT DO:
- (1) It **DOES NOT** warn of wind shear outside of the alert boxes (on the arrival and departure ends of the runways);
 - (2) It **DOES NOT** detect wind shear that is NOT a microburst or a gust front;
 - (3) It **DOES NOT** detect gusty or cross wind conditions; and
 - (4) It **DOES NOT** detect turbulence.

However, research and development is continuing on these systems. Future improvements may include such areas as storm motion (movement), improved gust front detection, storm growth and decay, microburst prediction, and turbulence detection.

- (c) TDWR also provides a geographical situation display (GSD) for supervisors and traffic management specialists for planning purposes. The GSD displays (in color) 6 levels of weather (precipitation), gust fronts and predicted storm movement(s). This data is used by the tower supervisor(s), traffic management specialists and

UNITED STATES

SECTION 1. METEOROLOGY

controllers to plan for runway changes and arrival/departure route changes in order to both reduce aircraft delays and increase airport capacity.

4. Weather Systems Processor (WSP).

- (a) The WSP provides the controller, supervisor, traffic management specialist, and ultimately the pilot, with the same products as the terminal doppler weather radar (TDWR) at a fraction of the cost of a TDWR. This is accomplished by utilizing new technologies to access the weather channel capabilities of the existing ASR-9 radar located on or near the airport, thus eliminating the requirements for a separate radar location, land acquisition, support facilities and the associated communication landlines and expenses.
- (b) The WSP utilizes the same RBDT display as the TDWR and LLWAS, and, just like TDWR, also has a GSD for planning purposes by supervisors, traffic management specialists and controllers. The WSP GSD emulates the TDWR display, i.e., it also depicts 6 levels of precipitation, gust fronts and predicted storm movement, and like the TDWR GSD, is used to plan for runway changes and arrival/departure route changes in order to reduce aircraft delays and to increase airport capacity.
- (c) This system is installed at 34 airports across the nation, substantially increasing the safety of flying.

5. Operational aspects of LLWAS, TDWR and WSP.

To demonstrate how this data is used by both the controller and the pilot, 3 ribbon display examples and their explanations are presented:

(a) MICROBURST ALERTS

EXAMPLE: This is what the controller sees on his/her ribbon display in the tower cab.

27A MBA 35K—2MF 250 20

NOTE: (See FIG 7-1-17 to see how the TDWR/WSP determines the microburst location).

This is what the controller will say when issuing the alert.

PHRASEOLOGY:

RUNWAY 27 ARRIVAL, MICROBURST ALERT, 35 KT LOSS 2 MILE FINAL, THRESHOLD WIND 250 AT 20.

In plain language, the controller is telling the pilot that on approach to runway 27, there is a microburst alert on the approach lane to the runway, and to anticipate or expect a 35 knot loss of airspeed at approximately 2 miles out on final approach (where it will first encounter the phenomena). With that information, the aircrew is forewarned, and should be prepared to apply wind shear/microburst escape proce-

UNITED STATES

SECTION 1. METEOROLOGY

dures should they decide to continue the approach. Additionally, the surface winds at the airport for landing runway 27 are reported as 250 degrees at 20 knots.

NOTE: *Threshold wind is at pilot's request or as deemed appropriate by the controller.*

REFERENCE—FAA Order JO 7110.65, Para 3-1-8b2(a), *Air Traffic Control, Low Level Wind Shear/Microburst Advisories.*

FIGURE 7-1-17

Microburst Alert

(b) WIND SHEAR ALERTS

EXAMPLE: This is what the controller sees on his/her ribbon display in the tower cab.

27A WSA 20K—3MF 200 15

NOTE: (See FIG 7-1-18 to see how the TDWR/WSP determines the wind shear location).

This is what the controller will say when issuing the alert.

PHRASEOLOGY:

RUNWAY 27 ARRIVAL, WIND SHEAR ALERT, 20 KT LOSS 3 MILE FINAL, THRESHOLD WIND 200 AT 15.

In plain language, the controller is advising the aircraft arriving on runway 27 that at about 3 miles out they can expect to encounter a wind shear condition that will decrease their airspeed by 20 knots and possibly encounter turbulence. Addition-

UNITED STATES
SECTION 1. METEOROLOGY

ally, the airport surface winds for landing runway 27 are reported as 200 degrees at 15 knots.

NOTE: *Threshold wind is at pilot's request or as deemed appropriate by the controller.*

REFERENCE—FAA Order JO 7110.65, *Air Traffic Control, Low Level Wind Shear/ Microburst Advisories, Paragraph 3-1-8b2(a).*

FIGURE 7-1-18

Weak Microburst Alert

(c) MULTIPLE WIND SHEAR ALERTS

EXAMPLE: This is what the controller sees on his/her ribbon display in the tower cab.

27A WSA 20K+ RWY 250 20

27D WSA 20K+ RWY 250 20

NOTE: (See FIG 7-1-19 to see how the TDWR/WSP determines the gust front/ wind shear location.)

This is what the controller will say when issuing the alert.

PHRASEOLOGY:

MULTIPLE WIND SHEAR ALERTS. RUNWAY 27 ARRIVAL, WIND SHEAR ALERT, 20 KT GAIN ON RUNWAY; RUNWAY 27 DEPARTURE, WIND SHEAR ALERT, 20 KT GAIN ON RUNWAY, WIND 250 AT 20.

EXAMPLE: In this example, the controller is advising arriving and departing aircraft that they could encounter a wind shear condition right on the runway due to a

UNITED STATES
SECTION 1. METEOROLOGY

gust front (significant change of wind direction) with the possibility of a 20 knot gain in airspeed associated with the gust front. Additionally, the airport surface winds (for the runway in use) are reported as 250 degrees at 20 knots.

REFERENCE—FAA Order 7110.65, *Air Traffic Control, Low Level Wind Shear/ Microburst Advisories, Paragraph 3-1-8b2(d)*.

FIGURE 7-1-19

Gust Front Alert

6. The Terminal Weather Information for Pilots System (TWIP).

- (a) With the increase in the quantity and quality of terminal weather information available through TDWR, the next step is to provide this information directly to pilots rather than relying on voice communications from ATC. The National Airspace System has long been in need of a means of delivering terminal weather information to the cockpit more efficiently in terms of both speed and accuracy to enhance pilot awareness of weather hazards and reduce air traffic controller workload. With the TWIP capability, terminal weather information, both alphanumerically and graphically, is now available directly to the cockpit at 43 airports in the U.S. NAS. (See FIG 7-1-20.)

**UNITED STATES
SECTION 1. METEOROLOGY**

FIGURE 7-1-20

TWIP Image of Convective Weather at MCO International

WEATHER SITUATION	TWIP TEXT MESSAGE
	MCO 1800 TERMINAL WEATHER -STORM(S) 3NM N-E MOD PRECIP 4NM NE HVY PRECIP MOVG W AT 15KT .EXPECTED MOD PRECIP BEGIN 1805
	MCO 1810 TERMINAL WEATHER *MODERATE PRECIP BEGAN 1805 -STORM(S) ARPT ALQDS MOD PRECIP 1NM N-E HVY PRECIP MOVG W AT 15KT .EXPECTED HVY PRECIP BEGIN 1815

- (b) TWIP products are generated using weather data from the TDWR or the Integrated Terminal Weather System (ITWS). These products can then be accessed by pilots using the Aircraft Communications Addressing and Reporting System (ACARS) data link services. Airline dispatchers can also access this database and send messages to specific aircraft whenever wind shear activity begins or ends at an airport.
- (c) TWIP products include descriptions and character graphics of microburst alerts, wind shear alerts, significant precipitation, convective activity within 30 NM surrounding the terminal area, and expected weather that will impact airport operations. During inclement weather, i.e., whenever a predetermined level of precipitation or wind shear is detected within 15 miles of the terminal area, TWIP products are updated once each minute for text messages and once every five minutes for character graphic messages. During good weather (below the predetermined precipitation or wind shear parameters) each message is updated every 10 minutes. These products are intended to improve the situational awareness of the pilot/flight crew, and to aid in flight planning prior to arriving or departing the terminal area. It is important to understand that, in the context of TWIP, the predetermined levels for inclement versus good weather has nothing to do with the criteria for VFR/MVFR/IFR/LIFR; it only deals with precipitation, wind shears and microbursts.

7-1-25 PIREPs RELATING TO VOLCANIC ASH ACTIVITY

- a. Volcanic eruptions which send ash into the upper atmosphere occur somewhere around the world several times each year. Flying into a volcanic ash cloud can be extremely dangerous. At least two B747s have lost all power in all four engines after such an encounter. Regardless of the type aircraft, some damage is almost certain to ensue after an encounter with a volcanic ash cloud. Additionally, studies have shown that volcanic eruptions are the only significant source of large quantities of sulphur dioxide (SO₂) gas at jet-cruising altitudes. Therefore, the detection and subsequent reporting of SO₂ is of significant importance. Although SO₂ is colorless, its presence in the atmosphere should be suspected when a sulphur-like or rotten egg odor is present throughout the cabin.
- b. While some volcanoes in the U.S. are monitored, many in remote areas are not. These unmonitored volcanoes may erupt without prior warning to the aviation community. A pilot observing a volcanic eruption who has not had previous notification of it may be the only witness to the eruption. Pilots are strongly encouraged to transmit a PIREP regarding volcanic eruptions and any observed volcanic ash clouds or detection of sulphur dioxide (SO₂) gas associated with volcanic activity.
- c. Pilots should submit PIREPs regarding volcanic activity using the Volcanic Activity Reporting (VAR) form as illustrated in Appendix 2. If a VAR form is not immediately available, relay enough information to identify the position and type of volcanic activity.

UNITED STATES
SECTION 1. METEOROLOGY

- d. Pilots should verbally transmit the data required in items 1 through 8 of the VAR as soon as possible. The data required in items 9 through 16 of the VAR should be relayed after landing if possible.

7-1-26 THUNDERSTORMS

- a. Turbulence, hail, rain, snow, lightning, sustained updrafts and downdrafts, icing conditions—all are present in thunderstorms. While there is some evidence that maximum turbulence exists at the middle level of a thunderstorm, recent studies show little variation of turbulence intensity with altitude.
- b. There is no useful correlation between the external visual appearance of thunderstorms and the severity or amount of turbulence or hail within them. The visible thunderstorm cloud is only a portion of a turbulent system whose updrafts and downdrafts often extend far beyond the visible storm cloud. Severe turbulence can be expected up to 20 miles from severe thunderstorms. This distance decreases to about 10 miles in less severe storms.
- c. Weather radar, airborne or ground based, will normally reflect the areas of moderate to heavy precipitation (radar does not detect turbulence). The frequency and severity of turbulence generally increases with the radar reflectivity which is closely associated with the areas of highest liquid water content of the storm. **NO FLIGHT PATH THROUGH AN AREA OF STRONG OR VERY STRONG RADAR ECHOES SEPARATED BY 20-30 MILES OR LESS MAY BE CONSIDERED FREE OF SEVERE TURBULENCE.**
- d. Turbulence beneath a thunderstorm should not be minimized. This is especially true when the relative humidity is low in any layer between the surface and 15,000 feet. Then the lower altitudes may be characterized by strong out flowing winds and severe turbulence.
- e. The probability of lightning strikes occurring to aircraft is greatest when operating at altitudes where temperatures are between minus 5 degrees Celsius and plus 5 degrees Celsius. Lightning can strike aircraft flying in the clear in the vicinity of a thunderstorm.
- f. METAR reports do not include a descriptor for severe thunderstorms. However, by understanding severe thunderstorm criteria, i.e., 50 knot winds or $\frac{3}{4}$ inch hail, the information is available in the report to know that one is occurring.
- g. Current weather radar systems are able to objectively determine precipitation intensity. These precipitation intensity areas are described as “light,” “moderate,” “heavy,” and “extreme.”

REFERENCE—*Pilot/Controller Glossary — Precipitation Radar Weather Descriptions.*

EXAMPLE:

1. Alert provided by an ATC facility to an aircraft:
(aircraft identification) **EXTREME** precipitation between ten o'clock and two o'clock, one five miles. Precipitation area is two five miles in diameter.
2. Alert provided by an FSS:

UNITED STATES
SECTION 1. METEOROLOGY

(aircraft identification) EXTREME precipitation, two zero miles west of Atlanta V-O-R, two five miles wide, moving east at two zero knots, tops Flight Level three niner zero.

7-1-27 THUNDERSTORM FLYING

- a. Thunderstorm Avoidance. Never regard any thunderstorm lightly, even when radar echoes are of light intensity. Avoiding thunderstorms is the best policy. Following are some Do's and Don'ts of thunderstorm avoidance:
1. Don't land or takeoff in the face of an approaching thunderstorm. A sudden gust front of low level turbulence could cause loss of control.
 2. Don't attempt to fly under a thunderstorm even if you can see through to the other side. Turbulence and wind shear under the storm could be disastrous.
 3. Don't attempt to fly under the anvil of a thunderstorm. There is a potential for severe and extreme clear air turbulence.
 4. Don't fly without airborne radar into a cloud mass containing scattered embedded thunderstorms. Scattered thunderstorms not embedded usually can be visually circumnavigated.
 5. Don't trust the visual appearance to be a reliable indicator of the turbulence inside a thunderstorm.
 6. Don't assume that ATC will offer radar navigation guidance or deviations around thunderstorms.
 7. Don't use data-linked weather next generation weather radar (NEXRAD) mosaic imagery as the sole means for negotiating a path through a thunderstorm area (tactical maneuvering).
 8. Do remember that the data-linked NEXRAD mosaic imagery shows where the weather was, not where the weather is. The weather conditions depicted may be 15 to 20 minutes older than indicated on the display.
 9. Do listen to chatter on the ATC frequency for Pilot Weather Reports (PIREP) and other aircraft requesting to deviate or divert.
 10. Do ask ATC for radar navigation guidance or to approve deviations around thunderstorms, if needed.
 11. Do use data-linked weather NEXRAD mosaic imagery (for example, Flight Information Service-Broadcast (FIS-B)) for route selection to avoid thunderstorms entirely (strategic maneuvering).
 12. Do advise ATC, when switched to another controller, that you are deviating for thunderstorms before accepting to rejoin the original route.
 13. Do ensure that after an authorized weather deviation, before accepting to rejoin the original route, that the route of flight is clear of thunderstorms.

UNITED STATES
SECTION 1. METEOROLOGY

14. Do avoid by at least 20 miles any thunderstorm identified as severe or giving an intense radar echo. This is especially true under the anvil of a large cumulonimbus.
 15. Do circumnavigate the entire area if the area has 6/10 thunderstorm coverage.
 16. Do remember that vivid and frequent lightning indicates the probability of a severe thunderstorm.
 17. Do regard as extremely hazardous any thunderstorm with tops 35,000 feet or higher whether the top is visually sighted or determined by radar.
 18. Do give a PIREP for the flight conditions.
 19. Do divert and wait out the thunderstorms on the ground if unable to navigate around an area of thunderstorms.
 20. Do contact Flight Service for assistance in avoiding thunderstorms. Flight Service specialists have NEXRAD mosaic radar imagery and NEXRAD single site radar with unique features such as base and composite reflectivity, echo tops, and VAD wind profiles.
- b. If you cannot avoid penetrating a thunderstorm, following are some Do's before entering the storm:
1. Tighten your safety belt, put on your shoulder harness (if installed), and secure all loose objects.
 2. Plan and hold the course to take the aircraft through the storm in a minimum time.
 3. To avoid the most critical icing, establish a penetration altitude below the freezing level or above the level of -15°C .
 4. Verify that pitot heat is on and turn on carburetor heat or jet engine anti-ice. Icing can be rapid at any altitude and cause almost instantaneous power failure and/or loss of air-speed indication.
 5. Establish power settings for turbulence penetration airspeed recommended in the aircraft manual.
 6. Turn up cockpit lights to highest intensity to lessen temporary blindness from lightning.
 7. If using automatic pilot, disengage Altitude Hold Mode and Speed Hold Mode. The automatic altitude and speed controls will increase maneuvers of the aircraft thus increasing structural stress.
 8. If using airborne radar, tilt the antenna up and down occasionally. This will permit the detection of other thunderstorm activity at altitudes other than the one being flown.
- c. Following are some Do's and Don'ts during the thunderstorm penetration:
1. Do keep your eyes on your instruments. Looking outside the cockpit can increase danger of temporary blindness from lightning.
 2. Don't change power settings; maintain settings for the recommended turbulence penetration airspeed.

UNITED STATES
SECTION 1. METEOROLOGY

3. Do maintain constant attitude. Allow the altitude and airspeed to fluctuate.
4. Don't turn back once you are in the thunderstorm. A straight course through the storm most likely will get the aircraft out of the hazards most quickly. In addition, turning maneuvers increase stress on the aircraft.

Table of Significant Present, Forecast and Recent Weather- Grouped in categories and used in the order listed below; or as needed in TAF, No Significant Weather.

Qualifiers Intensity or Proximity			
"-" = Light		No sign = Moderate	"+" = Heavy
"VC" = Vicinity, but not at aerodrome. In the US METAR, 5 to 10 SM from the point of observation. In the US TAF, 5 to 10 SM from the center of the runway complex. Elsewhere, within 8000m.			
Descriptor			
BC – Patches	BL – Blowing	DR – Drifting	FZ – Freezing
MI – Shallow	PR – Partial	SH – Showers	TS – Thunderstorm
Weather Phenomena Precipitation			
DZ – Drizzle	GR – Hail	GS – Small Hail/Snow Pellets	
IC – Ice Crystals	PL – Ice Pellets	RA – Rain	SG – Snow grains
SN – Snow	UP – Unknown Precipitation in automated observations		
Obscuration			
BR – Mist (≥ 5/8SM)	DU – Widespread Dust	FG – Fog (<5/8SM)	FU – Smoke
HZ – Haze	PY – Spray	SA – Sand	VA – Volcanic ash
Other			
DS – Dust Storm	FC – Funnel Cloud	+FC – Tornado or Waterspout	
PO – Well developed dust or sand whirls		SQ – Squall	SS – Sandstorm
-Explanations in parentheses "()" indicate different worldwide practices. -Ceiling is not specified; defined as the lowest broken or overcast layer, or the vertical visibility. -NWS TAFs exclude BECMG groups and temperatur forecasts, NWS TAFs do not use PROB in the first 9 hours of a TAF; NWS METARs exclude trend forecasts. US Military TAFs include Turbulence and Icing groups.			

UNITED STATES
SECTION 1. METEOROLOGY

7-1-29 INTERNATIONAL CIVIL AVIATION ORGANIZATION (ICAO) WEATHER FORMATS

The U.S. uses the ICAO world standard for aviation weather reporting and forecasting. The World Meteorological Organization's (WMO) publication No. 782 "Aerodrome Reports and Forecasts" contains the base METAR and TAF code as adopted by the WMO member countries.

- a. Although the METAR code is adopted worldwide, each country is allowed to make modifications or exceptions to the code for use in their particular country, e.g., the U.S. will continue to use statute miles for visibility, feet for RVR values, knots for wind speed, and inches of mercury for altimetry. However, temperature and dew point will be reported in degrees Celsius. The U.S. reports prevailing visibility rather than lowest sector visibility. The elements in the body of a METAR report are separated with a space. The only exceptions are RVR, temperature, and dew point which are separated with a solidus (/). When an element does not occur, or cannot be observed, the preceding space and that element are omitted from that particular report. A METAR report contains the following sequence of elements in the following order:

1. Type of report.
2. ICAO Station Identifier.
3. Date and time of report.
4. Modifier (as required).
5. Wind.
6. Visibility.
7. Runway Visual Range (RVR).
8. Weather phenomena.
9. Sky conditions.
10. Temperature/dew point group.
11. Altimeter.
12. Remarks (RMK).

- b. The following paragraphs describe the elements in a METAR report.

1. **Type of report.** There are two types of report:

- (a) Aviation Routine Weather Report (METAR); and
- (b) Nonroutine (Special) Aviation Weather Report (SPECI).

The type of report (METAR or SPECI) will always appear as the lead element of the report.

2. **ICAO Station Identifier.** The METAR code uses ICAO 4-letter station identifiers. In the contiguous 48 States, the 3-letter domestic station identifier is prefixed with a "K;" i.e., the domestic identifier for Seattle is SEA while the ICAO identifier is KSEA. Elsewhere,

UNITED STATES

SECTION 1. METEOROLOGY

the first two letters of the ICAO identifier indicate what region of the world and country (or state) the station is in. For Alaska, all station identifiers start with "PA;" for Hawaii, all station identifiers start with "PH." Canadian station identifiers start with "CU," "CW," "CY," and "CZ." Mexican station identifiers start with "MM." The identifier for the western Caribbean is "M" followed by the individual country's letter; i.e., Cuba is "MU;" Dominican Republic "MD;" the Bahamas "MY." The identifier for the eastern Caribbean is "T" followed by the individual country's letter; i.e., Puerto Rico is "TJ." For a complete worldwide listing see ICAO Document 7910, Location Indicators.

3. **Date and Time of Report.** The date and time the observation is taken are transmitted as a six-digit date/time group appended with Z to denote Coordinated Universal Time (UTC). The first two digits are the date followed with two digits for hour and two digits for minutes.

EXAMPLE: 172345Z (the 17th day of the month at 2345Z)

4. **Modifier (As Required).** "AUTO" identifies a METAR/SPECI report as an automated weather report with no human intervention. If "AUTO" is shown in the body of the report, the type of sensor equipment used at the station will be encoded in the remarks section of the report. The absence of "AUTO" indicates that a report was made manually by an observer or that an automated report had human augmentation/backup. The modifier "COR" indicates a corrected report that is sent out to replace an earlier report with an error.

NOTE: *There are two types of automated stations, AO1 for automated weather reporting stations without a precipitation discriminator, and AO2 for automated stations with a precipitation discriminator. (A precipitation discriminator can determine the difference between liquid and frozen/freezing precipitation). This information appears in the remarks section of an automated report.*

5. **Wind.** The wind is reported as a five digit group (six digits if speed is over 99 knots). The first three digits are the direction the wind is blowing from, in tens of degrees referenced to true north, or "VRB" if the direction is variable. The next two digits is the wind speed in knots, or if over 99 knots, the next three digits. If the wind is gusty, it is reported as a "G" after the speed followed by the highest gust reported. The abbreviation "KT" is appended to denote the use of knots for wind speed.

EXAMPLE: 13008KT — wind from 130 degrees at 8 knots

08032G45KT — wind from 080 degrees at 32 knots with gusts to 45 knots

VRB04KT — wind variable in direction at 4 knots

00000KT — wind calm

210103G130KT — wind from 210 degrees at 103 knots with gusts to 130 knots

If the wind direction is variable by 60 degrees or more and the speed is greater than 6 knots, a variable group consisting of the extremes of the wind direction separated by a "v" will follow the prevailing wind group.

UNITED STATES
SECTION 1. METEOROLOGY

32012G22KT 280V350

- (a) **Peak Wind.** Whenever the peak wind exceeds 25 knots “PK WND” will be included in Remarks, e.g., PK WND 28045/1955 “Peak wind two eight zero at four five occurred at one nine five five.” If the hour can be inferred from the report time, only the minutes will be appended, e.g., PK WND 34050/38 “Peak wind three four zero at five zero occurred at three eight past the hour.”
- (b) **Wind shift.** Whenever a wind shift occurs, “WSHFT” will be included in remarks followed by the time the wind shift began, e.g., WSHFT 30 FROPA “Wind shift at three zero due to frontal passage.”

6. **Visibility.** Prevailing visibility is reported in statute miles with “SM” appended to it.

EXAMPLE: 7SM — seven statute miles

15 SM — fifteen statute miles

$\frac{1}{2}$ SM — one-half statute mile

- (a) **Tower/surface visibility.** If either visibility (tower or surface) is below four statute miles, the lesser of the two will be reported in the body of the report; the greater will be reported in remarks.
- (b) **Automated visibility.** ASOS/AWOS visibility stations will show visibility 10 or greater than 10 miles as “10SM.” AWOS visibility stations will show visibility less than $\frac{1}{4}$ statute mile as “M $\frac{1}{4}$ SM” and visibility 10 or greater than 10 miles as “10SM.”

***NOTE:** Automated sites that are augmented by human observer to meet service level requirements can report 0, $\frac{1}{16}$ SM, and $\frac{1}{8}$ SM visibility increments.*

- (c) **Variable visibility.** Variable visibility is shown in remarks (when rapid increase or decrease by $\frac{1}{2}$ statute mile or more and the average prevailing visibility is less than three miles) e.g., VIS 1V2 “visibility variable between one and two.”
- (d) **Sector visibility.** Sector visibility is shown in remarks when it differs from the prevailing visibility, and either the prevailing or sector visibility is less than three miles.

EXAMPLE: VIS N2 — visibility north two

7. **Runway Visual Range (When Reported).** “R” identifies the group followed by the runway heading (and parallel runway designator, if needed) “/” and the visual range in feet (meters in other countries) followed with “FT” (feet is not spoken).

- (a) **Variability Values.** When RVR varies (by more than on reportable value), the lowest and highest values are shown with “V” between them.
- (b) **Maximum/Minimum Range.** “P” indicates an observed RVR is above the maximum value for this system (spoken as “more than”). “M” indicates an observed RVR is below the minimum value which can be determined by the system (spoken as “less than”).

UNITED STATES
SECTION 1. METEOROLOGY

EXAMPLE: R32L/1200FT — runway three two left R-V-R one thousand two hundred.

R27R/M1000V4000FT — runway two seven right R-V-R variable from less than one thousand to four thousand.

8. **Weather Phenomena.** The weather as reported in the METAR code represents a significant change in the way weather is currently reported. In METAR, weather is reported in the format:

Intensity/Proximity/Descriptor/Precipitation/Obstruction to visibility/Other

NOTE: The “/” above and in the following descriptions (except as the separator between the temperature and dew point) are for separation purposes in this publication and do not appear in the actual METARs.

- (a) **Intensity** applies only to the first type of precipitation reported. A “-” denotes light, no symbol denotes moderate, and a “+” denotes heavy.
- (b) **Proximity** applies to and reported only for weather occurring in the vicinity of the airport (between 5 and 10 miles of the point(s) of observation). It is denoted by the letters “VC.” (Intensity and “VC.” will not appear together in the weather group).
- (c) **Descriptor.** These eight descriptors apply to the precipitation or obstructions to visibility:

TS — thunderstorm

DR — low drifting

SH — showers

MI — shallow

FZ — freezing

BC — patches

BL — blowing

PR — partial

NOTE: Although “TS” and “SH” are used with precipitation and may be preceded with an intensity symbol, the intensity still applies to the precipitation, not the descriptor.

- (d) **Precipitation.** There are nine types of precipitation in the METAR code:

RA — rain

DZ — drizzle

SN — snow

GR — hail ($\frac{1}{4}$ ” or greater)

UNITED STATES
SECTION 1. METEOROLOGY

GS — small hail/snow pellets

PL — ice pellets

SG — snow grains

IC — ice crystals (diamond dust)

UP — unknown precipitation (automated stations only)

- (e) **Obstructions to visibility.** There are eight types of obscuration phenomena in the METAR code (obscurations are any phenomena in the atmosphere, other than precipitation, that reduce horizontal visibility):

FG — fog (vsby less than $\frac{5}{8}$ mile)

HZ — haze

FU — smoke

PY — spray

BR — mist (vsby $\frac{5}{8}$ — 6 miles)

SA — sand

DU — dust

VA — volcanic ash

NOTE: Fog (FG) is observed or forecast only when the visibility is less than five-eighths of mile, otherwise mist (BR) is observed or forecast.

- (f) **Other.** There are five categories of other weather phenomena which are reported when they occur:

SQ — squall

SS — sandstorm

DS — duststorm

PO — dust/sand whirls

FC — funnel cloud

+FC — tornado/waterspout

Examples:

TSRA — thunderstorm with moderate rain

+SN — heavy snow

-RA FG — light rain and fog

BRHZ — mist and haze (visibility $\frac{5}{8}$ mile or greater)

FZDZ — freezing drizzle

UNITED STATES
SECTION 1. METEOROLOGY

VCSH — rain shower in the vicinity

+SHRASNPL — heavy rain showers, snow, ice pellets (intensity indicator refers to the predominant rain)

9. **Sky Condition.** The sky condition as reported in METAR represents a significant change from the way sky condition is currently reported. In METAR, sky condition is reported in the format:

Amount/Height/(Type) or Indefinite Ceiling/Height

- (a) **Amount.** The amount of sky cover is reported in eighths of sky cover, using the contractions:

SKC — clear (no clouds)

FEW — >0 to $2/8$

SCT — scattered ($3/8$ s to $4/8$ s of clouds)

BKN — broken ($5/8$ s to $7/8$ s of clouds)

OVC — overcast ($8/8$ s clouds)

CB — Cumulonimbus when present

TCU — Towering cumulus when present

NOTE:

1. *“SKC” will be reported at manual stations. “CLR” will be used at automated stations when no clouds below 12,000 feet are reported.*
 2. *A ceiling layer is not designated in the METAR code. For aviation purposes, the ceiling is the lowest broken or overcast layer, or vertical visibility into an obscuration. Also there is no provision for reporting thin layers in the METAR code. When clouds are thin, that layer must be reported as if it were opaque.*
- (b) **Height.** Cloud bases are reported with three digits in hundreds of feet above ground level (AGL). (Clouds above 12,000 feet cannot be reported by an automated station).
- (c) **(Type).** If Towering Cumulus Clouds (TCU) or Cumulonimbus Clouds (CB) are present, they are reported after the height which represents their base.

EXAMPLE: (Reported as) SCT025TCU BKN080 BKN250 (spoken as) “TWO THOUSAND FIVE HUNDRED SCATTERED TOWERING CUMULUS, CEILING EIGHT THOUSAND BROKEN, TWO FIVE THOUSAND BROKEN.”

(Reported as) SCT008 OVC012CB (spoken as) “EIGHT HUNDRED SCATTERED CEILING ONE THOUSAND TWO HUNDRED OVERCAST CUMULONIMBUS CLOUDS.”

UNITED STATES

SECTION 1. METEOROLOGY

- (d) **Vertical Visibility (indefinite ceiling height).** The height into an indefinite ceiling is preceded by “VV” and followed by three digits indicating the vertical visibility in hundreds of feet. This layer indicates total obscuration.

EXAMPLE: $\frac{1}{8}$ SM FG VV006 — visibility one eighth, fog, indefinite ceiling six hundred.

- (e) **Obscurations** are reported when the sky is partially obscured by a ground-based phenomena by indicating the amount of obscuration as FEW, SCT, BKN followed by three zeros (000). In remarks, the obscuring phenomenon precedes the amount of obscuration and three zeros.

EXAMPLE: BKN000 (in body) — “sky partially obscured”

FU BKN000 (in remarks) — “smoke obscuring five-to seven-eighths of the sky”

- (f) When sky conditions include a layer aloft, other than clouds, such as smoke or haze the type of phenomena, sky cover and height are shown in remarks.

EXAMPLE: BKN020 (in body) — “ceiling two thousand broken”

RMK FU BKN020 — “broken layer of smoke aloft, based at two thousand”

- (g) **Variable ceiling.** When a ceiling is below three thousand and is variable, the remark “CIG” will be shown followed with the lowest and highest ceiling heights separated by a “V.”

EXAMPLE: CIG 005V010 — “ceiling variable between five hundred and one thousand”

- (h) **Second site sensor.** When an automated station uses meteorological discontinuity sensors, remarks will be shown to identify site specific sky conditions which differ and are lower than conditions reported in the body.

EXAMPLE: CIG 020 RY11 — “ceiling two thousand at runway one one”

- (i) **Variable cloud layer.** When a layer is varying in sky cover, remarks will show the variability range. If there is more than one cloud layer, the variable layer will be identified by including the layer height.

EXAMPLE: SCT V BKN — “scattered layer variable to broken”

BKN025 V OVC — “broken layer at two thousand five hundred variable to over-cast”

- (j) **Significant clouds.** When significant clouds are observed, they are shown in remarks, along with the specified information as shown below:

- (1) Cumulonimbus (CB), or Cumulonimbus Mammatus (CBMAM), distance (if known), direction from the station, and direction of movement, if known. If the clouds are beyond 10 miles from the airport, DSNT will indicate distance.

EXAMPLE: CB W MOV E — “cumulonimbus west moving east”

UNITED STATES
SECTION 1. METEOROLOGY

CBMAM DSNT S — “cumulonimbus mammatus distant south”

- (2) Towering Cumulus (TCU), location, (if known), or direction from the station.

EXAMPLE: TCU OHD — “towering cumulus overhead”

TCU W — “towering cumulus west”

- (3) Altocumulus Castellanus (ACC), Stratocumulus Standing Lenticular (SCSL), Altocumulus Standing Lenticular (ACSL), Cirrocumulus Standing Lenticular (CCSL) or rotor clouds, describing the clouds (if needed) and the direction from the station.

EXAMPLE: ACC W — “altocumulus castellanus west”

ACSL SW-S — “standing lenticular altocumulus southwest through south”

APRNT ROTOR CLD S — “apparent rotor cloud south”

CCSL OVR MT E — “standing lenticular cirrocumulus over the mountains east”

10. **Temperature/Dew Point.** Temperature and dew point are reported in two, two-digit groups in degrees Celsius, separated by a solidus (“/”). Temperatures below zero are prefixed with an “M.” If the temperature is available but the dew point is missing, the temperature is shown followed by a solidus. If the temperature is missing, the group is omitted from the report.

EXAMPLE: 15/08 — “temperature one five, dew point 8”

00/M02 — “temperature zero, dew point minus 2”

M05/ — “temperature minus five, dew point missing”

11. **Altimeter.** Altimeter settings are reported in a four-digit format in inches of mercury prefixed with an “A” to denote the units of pressure.

EXAMPLE: A2995 — “Altimeter two niner niner five”

12. **Remarks.** Remarks will be included in all observations, when appropriate. The contraction “RMK” denotes the start of the remarks section of a METAR report.

Except for precipitation, phenomena located within 5 statute miles of the point of observation will be reported as at the station. Phenomena between 5 and 10 statute miles will be reported in the vicinity, “VC.” Precipitation not occurring at the point of observation but within 10 statute miles is also reported as in the vicinity, “VC.” Phenomena beyond 10 statute miles will be shown as distant, “DSNT.” Distances are in statute miles except for automated lightning remarks which are in nautical miles. Movement of clouds or weather will be indicated by the direction toward which the phenomena is moving.

- (a) There are two categories of remarks:

- (1) Automated, manual, and plain language.

UNITED STATES
SECTION 1. METEOROLOGY

- (2) Additive and automated maintenance data.
- (b) **Automated, Manual, and Plain Language.** This group of remarks may be generated from either manual or automated weather reporting stations and generally elaborate on parameters reported in the body of the report. (Plain language remarks are only provided by manual stations).

- (1) Volcanic eruptions.
 - (2) Tornado, Funnel Cloud, Waterspout.
 - (3) Station Type (AO1 or AO2).
 - (4) PK WND.
 - (5) WSHFT (FROPA).
 - (6) TWR VIS or SFC VIS.
 - (7) VRB VIS.
 - (8) Sector VIS.
 - (9) VIS @ 2nd Site.
- (10) Lightning. When lightning is observed at a manual location, the frequency and location is reported.

When cloud-to-ground lightning is detected by an automated lightning detection system, such as ALDARS:

- [a] Within 5 nautical miles (NM) of the Airport Reference Point (ARP), it will be reported as "TS" in the body of the report with no remark;
- [b] Between 5 and 10 NM of the ARP, it will be reported as "VCTS" in the body of the report with no remark;
- [c] Beyond 10 but less than 30 NM of the ARP, it will be reported in remarks as "DSNT" followed by the direction from the ARP.

EXAMPLE: LTG DSNT W or LTG DSNT ALQDS

- (11) Beginning/Ending of Precipitation/TSTMS.
- (12) TSTM Location MVMT.
- (13) Hailstone Size (GR).
- (14) Virga.
- (15) VRB CIG (height).
- (16) Obscuration.
- (17) VRB Sky Condition.
- (18) Significant Cloud Types.
- (19) Ceiling Height 2nd Location.

**UNITED STATES
SECTION 1. METEOROLOGY**

- (20) PRESFR PRESRR.
- (21) Sea-Level Pressure.
- (22) ACFT Mishap (not transmitted).
- (23) NOSPECI.
- (24) SNINCR.
- (25) Other SIG Info.

(c) Additive and Automated Maintenance Data.

- (1) Hourly Precipitation.
- (2) 3-and 6-Hour Precipitation Amount.
- (3) 24-Hour Precipitation.
- (4) Snow Depth on Ground.
- (5) Water Equivalent of Snow.
- (6) Cloud Type.
- (7) Duration of Sunshine.
- (8) Hourly Temperature/Dew Point (Tenths).
- (9) 6-Hour Maximum Temperature.
- (10) 6-Hour Minimum Temperature.
- (11) 24-Hour Maximum/Minimum Temperature.
- (12) Pressure Tendency.
- (13) Sensor Status.

- c. **Aerodrome Forecast (TAF).** A concise statement of the expected meteorological conditions at an airport during a specified period. At most locations, TAFs have a 24 hour forecast period. However, TAFs for some locations have a 30 hour forecast period. These forecast periods may be shorter in the case of an amended TAF. TAFs use the same codes as METAR weather reports. They are scheduled four times daily for 24-hour periods beginning at 0000Z, 0600Z, 1200Z, and 1800Z.

Forecast times in the TAF are depicted in two ways. The first is a 6-digit number to indicate a specific point in time, consisting of a two-digit date, two-digit hour, and two-digit minute (such as issuance time or FM). The second is a pair of four-digit numbers separated by a "/" to indicate a beginning and end for a period of time. In this case, each four-digit pair consists of a two-digit date and a two-digit hour.

TAFs are issued in the following format:

TYPE OF REPORT/ICAO STATION IDENTIFIER/DATE AND TIME OF ORIGIN/VALID
PERIOD DATE AND TIME/FORECAST METEOROLOGICAL CONDITIONS

UNITED STATES
SECTION 1. METEOROLOGY

NOTE: The “/” above and in the following descriptions are for separation purposes in this publication and do not appear in the actual TAFs.

TAF KORD 051130Z 0512/0618 14008KT 5SM BR BKN030

TEMPO 0513/0516 1 1/2SM BR

FM051600 16010KT P6SM SKC

FM052300 20013G20KT 4SM SHRA OVC020

PROB40 0600/0606 2SM TSRA OVC008CB

BECMG 0606/0608 21015KT P6SM NSW

SCT040

TAF format observed in the above example:

TAF = type of report

KORD = ICAO station identifier

051130Z = date and time of origin (issuance time)

0512/0618 = valid period date and times

14008KT 5SM BR BKN030 = forecast meteorological conditions

Explanation of TAF elements:

- 1. Type of Report.** There are two types of TAF issuances, a routine forecast issuance (TAF) and an amended forecast (TAF AMD). An amended TAF is issued when the current TAF no longer adequately describes the on-going weather or the forecaster feels the TAF is not representative of the current or expected weather. Corrected (COR) or delayed (RTD) TAFs are identified only in the communications header which precedes the actual forecasts.
- 2. ICAO Station Identifier.** The TAF code uses ICAO 4-letter location identifiers as described in the METAR section.
- 3. Date and Time of Origin.** This element is the date and time the forecast is actually prepared. The format is a two-digit date and four-digit time followed, without a space, by the letter “Z.”
- 4. Valid Period Date and Time.** The UTC valid period of the forecast consists of two four-digit sets, separated by a “/”. The first four-digit set is a two-digit date followed by the two-digit beginning hour, and the second four-digit set is a two-digit date followed by the two-digit ending hour. Although most airports have a 24-hour TAF, a select number of airports have a 30-hour TAF. In the case of an amended forecast, or a forecast which is corrected or delayed, the valid period may be for less than 24 hours. Where an airport or terminal operates on a part-time basis (less than 24 hours/day), the TAFs issued for those locations will have the abbreviated statement “AMD NOT SKED” added to the end of the forecasts. The time observations are scheduled to end and/or resume will be

UNITED STATES
SECTION 1. METEOROLOGY

indicated by expanding the AMD NOT SKED statement. Expanded statements will include:

- (a) Observation ending time (AFT DDHHmm; for example, AFT 120200)
- (b) Scheduled observations resumption time (TIL DDHHmm; for example, TIL 171200Z) or
- (c) Period of observation unavailability (DDHH/DDHH); for example, 2502/2512).

5. Forecast Meteorological Conditions. This is the body of the TAF. The basic format is:
WIND/VISIBILITY/WEATHER/SKY CONDITION/OPTIONAL DATA (WIND SHEAR)

The wind, visibility, and sky condition elements are always included in the initial time group of the forecast. Weather is included only if significant to aviation. If a significant, lasting change in any of the elements is expected during the valid period, a new time period with the changes is included. It should be noted that with the exception of a "FM" group the new time period will include only those elements which are expected to change, i.e., if a lowering of the visibility is expected but the wind is expected to remain the same, the new time period reflecting the lower visibility would not include a forecast wind. The forecast wind would remain the same as in the previous time period. Any temporary conditions expected during a specific time period are included with that time period. The following describes the elements in the above format.

- (a) **Wind.** This five (or six) digit group includes the expected wind direction (first 3 digits) and speed (last 2 digits or 3 digits if 100 knots or greater). The contraction "KT" follows to denote the units of wind speed. Wind gusts are noted by the letter "G" appended to the wind speed followed by the highest expected gust. A variable wind direction is noted by "VRB" where the three digit direction usually appears. A calm wind (3 knots or less) is forecast as "00000KT."

EXAMPLE: 18010KT — wind one eight zero at one zero (wind is blowing from 180).

35012G20KT — wind three five zero at one two gust two zero.

- (b) **Visibility.** The expected prevailing visibility up to and including 6 miles is forecast in statute miles, including fractions of miles, followed by "SM" to note the units of measure. Expected visibilities greater than 6 miles are forecast as P6SM (plus six statute miles).

EXAMPLE: $\frac{1}{2}$ SM — visibility one-half

4SM — visibility four

P6SM — visibility more than six

- (c) **Weather Phenomena.** The expected weather phenomena is coded in TAF reports using the same format, qualifiers, and phenomena contractions as METAR reports (except UP). Obscurations to vision will be forecast whenever the prevailing visibility is forecast to be 6 statute miles or less. If no significant weather is expected to

UNITED STATES

SECTION 1. METEOROLOGY

occur during a specific time period in the forecast, the weather phenomena group is omitted for that time period. If, after a time period in which significant weather phenomena has been forecast, a change to a forecast of no significant weather phenomena occurs, the contraction NSW (No Significant Weather) will appear as the weather group in the new time period. (NSW is included only in TEMPO groups).

NOTE: *It is very important that pilots understand that NSW only refers to weather phenomena, i.e., rain, snow, drizzle, etc. Omitted conditions, such as sky conditions, visibility, winds, etc., are carried over from the previous time group.*

- (d) **Sky Condition.** TAF sky condition forecasts use the METAR format described in the METAR section. Cumulonimbus clouds (CB) are the only cloud type forecast in TAFs. When clear skies are forecast, the contraction “SKC” will always be used. The contraction “CLR” is never used in the TAF. When the sky is obscured due to a surface-based phenomenon, vertical visibility (VV) into the obscuration is forecast. The format for vertical visibility is “VV” followed by a three-digit height in hundreds of feet.

NOTE: *As in METAR, ceiling layers are not designated in the TAF code. For aviation purposes, the ceiling is the lowest broken or overcast layer or vertical visibility into a complete obscuration.*

SKC — “sky clear”

SCT005 BKN025CB — “five hundred scattered, ceiling two thousand five hundred broken cumulonimbus clouds”

VV008 — “indefinite ceiling eight hundred”

- (e) **Optional Data (Wind Shear).** Wind shear is the forecast of nonconvective low level winds (up to 2,000 feet). The forecast includes the letters “WS” followed by the height of the wind shear, the wind direction and wind speed at the indicated height and the ending letters “KT” (knots). Height is given in hundreds of feet (AGL) up to and including 2,000 feet. Wind shear is encoded with the contraction “WS,” followed by a three-digit height, slant character “/,” and winds at the height indicated in the same format as surface winds. The wind shear element is omitted if not expected to occur.

WS010/18040KT — “LOW LEVEL WIND SHEAR AT ONE THOUSAND, WIND ONE EIGHT ZERO AT FOUR ZERO”

- d. **Probability Forecast.** The probability or chance of thunderstorms or other precipitation events occurring, along with associated weather conditions (wind, visibility, and sky conditions). The PROB30 group is used when the occurrence of thunderstorms or precipitation is 30-39% and the PROB40 group is used when the occurrence of thunderstorms or precipitation is 40-49%. This is followed by two four-digit groups separated by a “/”, giving the beginning date and hour, and the ending date and hour of the time period during which the thunderstorms or precipitation are expected.

UNITED STATES

SECTION 1. METEOROLOGY

NOTE: NWS does not use PROB 40 in the TAF. However U.S. Military generated TAFS may include PROB40. PROB30 will not be shown during the first nine hours of a NWS forecast.

EXAMPLE: PROB40 2221/2302 1/2 SM +TSRA “chance between 2100Z and 0200Z of visibility one-half statute mile in thunderstorms and heavy rain.”

PROB30 3010/3014 1SM RASN. “chance between 1000Z and 1400Z of visibility one statute mile in mixed rain and snow.”

- e. **Forecast Change Indicators.** The following change indicators are used when either a rapid, gradual, or temporary change is expected in some or all of the forecast meteorological conditions. Each change indicator marks a time group within the TAF report.

1. From (FM) group. The FM group is used when a rapid change, usually occurring in less than one hour, in prevailing conditions is expected. Typically, a rapid change of prevailing conditions to more or less a completely new set of prevailing conditions is associated with a synoptic feature passing through the terminal area (cold or warm frontal passage). Appended to the “FM” indicator is the six-digit date, hour, and minute the change is expected to begin and continues until the next change group or until the end of the current forecast. A “FM” group will mark the beginning of a new line in a TAF report (indented 5 spaces). Each “FM” group contains all the required elements—wind, visibility, weather, and sky condition. Weather will be omitted in “FM” groups when it is not significant to aviation. FM groups will not include the contraction NSW.

EXAMPLE: FM210100 14010KT P6SM SKC — “after 0100Z on the 21st, wind one four zero at one zero, visibility more than six, sky clear.”

2. Becoming (BECMG) group. The BECMG group is used when a gradual change in conditions is expected over a longer time period, usually two hours. The time period when the change is expected is two four-digit groups separated by a “/”, with the beginning date and hour, and ending date and hour of the change period which follows the BECMG indicator. The gradual change will occur at an unspecified time within this time period. Only the changing forecast meteorological conditions are included in BECMG groups. The omitted conditions are carried over from the previous time group.

NOTE: The NWS does not use BECMG in the TAF.

EXAMPLE: OVC012 BECMG 0114/0116 BKN020 — “ceiling one thousand two hundred overcast. Then a gradual change to ceiling two thousand broken between 1400Z on the 1st and 1600Z on the 1st.”

3. Temporary (TEMPO) group. The TEMPO group is used for any conditions in wind, visibility, weather, or sky condition which are expected to last for generally less than an hour at a time (occasional), and are expected to occur during less than half the time period. The TEMPO indicator is followed by two four-digit groups separated by a “/”. The first four digit group gives the beginning date and hour, and the second four digit group gives the ending date and hour of the time period during which the temporary conditions are expected. Only the changing forecast meteorological conditions are

UNITED STATES
SECTION 1. METEOROLOGY

included in TEMPO groups. The omitted conditions are carried over from the previous time group.

EXAMPLE:

1. SCT030 TEMPO 0519/0523 BKN030 — “three thousand scattered with occasional ceilings three thousand broken between 1900Z on the 5th and 2300Z on the 5th.”
2. 4SM HZ TEMPO 1900/1906 2SM BR HZ — “visibility four in haze with occasional visibility two in mist and haze between 0000Z on the 19th and 0600Z on the 19th.”

Air Traffic Control

Air Traffic Control

State Rules and Procedures - Canada

**CA 1
GENERAL****SECTION 1**

Canadian Aviation Regulations (CARs) may be referenced in the text of this section; however, they are not necessarily published herein.

1.1 AIR TRAFFIC AND ADVISORY SERVICES

The following is a list of control advisory and information services that are available to pilots.

1.1.1 Air Traffic Services

The following air traffic control and information services are provided by ACCs and TWRs.

- a. Airport control service is provided by airport TWRs to aircraft and vehicles on the maneuvering area of an airport and to aircraft operating in the vicinity of an airport.
- b. Area control service is provided by ACCs to IFR and CVFR flights operating within specified control areas.
- c. Terminal control service is provided by ACCs to IFR and CVFR flights operating within specified control areas.
- d. Terminal control service is additional service provided by IFR units to VFR aircraft operating within Class C airspace.
- e. Alerting service notifies appropriate organizations regarding aircraft in need of search and rescue services, or alerts crash equipment, ambulances, doctors and any other safety services.
- f. Altitude reservation service provides mission planning support for altitude reservations (ALTRVs) and other military activities, airspace coordination for military or specialized operations in controlled airspace, coordination with user agencies and affected ATS units, and issuing approvals and clearances for aircraft to operate within approved ALTRVs.
- g. Aircraft Movement Information Service (AMIS) is provided by ACCs for the collection, processing and dissemination of aircraft movement information for use by Air Defence Units relative to flights operating into or within Canadian Air Defence Identification Zones (ADIZ).
 1. Flight information service is provided by ATC units to assist pilots of aircraft by supplying information concerning known hazardous flight conditions. This information will include data concerning unfavorable flight conditions and other known hazards, which may not have been available to the pilot prior to takeoff or which may have developed along the route of flight.

The ATC service has been established primarily for the prevention of collisions and the expediting of traffic. The provision of such service will take precedence over the provision of flight information service, but every effort will be made to provide flight information and assistance.

Flight information will be made available, whenever practicable, to any aircraft in communication with an ATC unit, prior to takeoff or when in flight, except where such service is provided by the aircraft operator. Many factors (such as volume of traffic, controller workload, communications frequency congestion and limitations of ATS surveillance equipment) may prevent a controller from providing this service.

**CA 1
GENERAL**

VFR flights will be provided with information concerning:

- a. severe weather conditions along the proposed route of flight;
- b. changes in the serviceability of navigation aids;
- c. conditions of airports and associated facilities; and
- d. other items considered pertinent to safety of flight.

IFR flights will be provided with information concerning:

- a. severe weather conditions;
- b. weather conditions reported or forecast at destination or alternate airport;
- c. changes in the serviceability of navigation aids;
- d. condition of airports and associated facilities; and
- e. other items considered pertinent to the safety of flight.

Flight information messages are intended as information only. If a specific action is suggested, the message will be prefixed by the term "ATC SUGGESTS..." or "SUGGEST YOU..." and the pilot will be informed of the purpose of the suggested action. The pilot is responsible for making the final decision concerning any suggestion.

ATS surveillance equipment is frequently used in the provision of information concerning hazards, such as chaff drops, bird activity and possible traffic conflicts. Due to limitations inherent in all ATS surveillance systems, aircraft, chaff, etc., cannot be detected in all cases.

Whenever practicable, ATC will provide flights with severe weather information pertinent to the area concerned. Pilots may assist ATC by providing pilot reports of severe weather conditions they encounter. ATC will endeavour to suggest alternate routes available in order to avoid areas experiencing severe weather.

ATC will provide pilots intending to operate through chaff areas with all available information relating to proposed or actual chaff drops:

- a. location of chaff drop area;
- b. time of drop;
- c. estimated speed and direction of drift;
- d. altitudes likely to be affected; and
- e. relative intensity of chaff.

Information concerning bird activity, obtained through controller's observations or pilot reports, will be provided to aircraft operating in the area concerned. In addition, pilots may be warned of possible bird hazards if ATS surveillance observation indicates the possibility of bird activity. Information will be provided concerning:

- a. size or species of bird, if known;
- b. location;

**CA 1
GENERAL**

- c. direction of flight; and
- d. altitude, if known.

ATS surveillance traffic information and ATS surveillance navigation assistance to VFR flights are contained in ATC para 1.5.

1.1.2 Flight Advisory and Information Service

The following flight advisory and information services are provided by FICs and FSSs.

1.1.2.1 Flight Information Centers (FICs)

- a. *Pilot briefing service*: the provision of, or consultation on, meteorological and aeronautical information to assist pilots in pre-flight planning for the safe and efficient conduct of flight. The flight service specialist adapts meteorological information, including satellite and radar imagery, to fit the needs of flight crew members and operations personnel, and provides consultation and advice on special weather problems. Flight service specialists accept flight plan information during a briefing.
- b. *FISE*: the exchange on the FISE frequency of information pertinent to the enroute phase of flight. Aircraft traffic information is not provided. Upon request from an aircraft, a FIC provides:
 - 1. meteorological information: SIGMET, AIRMET, PIREP, aviation routine weather report (METAR), aviation selected special weather report (SPECI), airport forecast (TAF), altimeter setting, weather radar, lightning information and briefing update;
 - 2. aeronautical information: NOTAM, RSC, CRFI, MANOT and other information of interest for flight safety; and
 - 3. relay of communications with ATC: IFR clearance and SVFR authorization.

Enroute aircraft may submit to a FIC: PIREPs, IFR and VFR position reports (including arrival and departure times), revised flight plan or flight itinerary information and other reports, such as vital intelligence sightings (CIRVIS) and pollution reports. Fuel dumping information may also be submitted for coordination with the appropriate ACC and for aeronautical broadcast needs.

- c. *Aeronautical broadcast service*: the broadcast on the FISE frequency and 126.7 MHz of SIGMET, urgent PIREP and information concerning fuel dumping operations.
- d. *VFR flight plan alerting service*: the notification of RCCs and provision of communications searches when an aircraft on a VFR flight plan or flight itinerary becomes overdue and needs SAR aid.
- e. *Flight Regularity Message Service*: the relay by FICs of messages between an aircraft in-flight and the aircraft operating agency, and vice versa, when an agency with AFTN access subscribes to the service for an annual cost. Agencies interested in subscribing to this service should contact the NAV CANADA Customer Service Center.

**CA 1
GENERAL****1.1.2.2 *Flight Service Stations (FSSs)***

- a. *Airport advisory service (AAS)*: the provision of information pertinent to the arrival and departure phases of flight at uncontrolled airports and for transit through an MF area. AAS is provided on the MF and is normally in conjunction with VCS.

The elements of information listed below are provided, if appropriate, by the flight service specialist during initial airport advisory communications with an aircraft:

1. runway;
2. wind direction and speed;
3. aircraft traffic that warrants attention;
4. vehicle traffic
5. wake turbulence cautionary;
6. airport conditions;
7. weather conditions; and
8. additional information of interest for the safety of flight.

The flight service specialist updates this information, when appropriate, after the initial advisory. Pilots are encouraged to indicate in initial transmissions to the FSS that information from the ATIS or from an AWOS (or LWIS) broadcast, or use the phrase “HAVE NUMBERS” if runway, wind and altimeter information from the previous airport advisory have been received, so that the flight service specialist does not repeat the information.

Mandatory reports by aircraft on the MF are critical for the FSS to be able to provide effective air traffic information. At certain FSS locations, air traffic information may also be based on situation display. A pilot remains responsible for avoidance of traffic in Class E airspace.

Communication regarding TCAS events and displayed information should be limited to that required to inform the flight service specialist that the aircraft is responding to an RA. Discretion should be used in using the TCAS traffic display to ask questions regarding traffic in the vicinity of an aircraft. As would be expected, aircraft shown on a TCAS display may not match the traffic information provided by the flight service specialist.

NOTAM, runway surface condition (RSC) and Canadian Runway Friction Index (CRFI) are included in advisories for a period of 12 hr for domestic traffic, and 24 hr for international traffic, after dissemination by means of telecommunication. Airport conditions published prior to these time limits should have been received in the pilot briefing or can be obtained on request.

Airport lighting is operated by the FSS, unless otherwise indicated in the Airport Directory. The flight service specialist relays ATC clearances, special VFR authorizations and routinely informs the ACC of all IFR arrival times. The specialist also relays a VFR arrival report to a FIC upon request from an aircraft.

CA 1 GENERAL

Pilots should be aware that a flight service specialist will alert appropriate agencies for any aircraft, which has received a landing advisory for an airport that lies within a MF area and within radio communication range, if it fails to arrive within 5 minutes of its latest ETA, and communication cannot be re-established with the aircraft.

- b. *VCS*: the provision, at locations where AAS is provided, of instructions to control the movements of vehicle, equipment and pedestrians on maneuvering areas of uncontrolled airports. Flight service specialists will normally instruct vehicle traffic to leave the intended runway at least 5 minutes prior to the estimated time of landing or before a departing aircraft enters the maneuvering area. The specialist will coordinate with the pilot prior to authorizing traffic to operate on the intended runway within less than 5 minutes of the estimated time of landing or the time an aircraft is ready for takeoff.

1.1.2.3 *Flight Information Centres (FICs) and Flight Service Stations (FSSs)*

- a. *RAAS*: the provision, via remote communications outlets (RCO), of information pertinent to the arrival and departure phases of flight and for transit through an MF area.

RAAS consists in the issuance of the same type of information as in AAS, except that it is provided from a remote location. It is emphasized that the flight service specialist cannot observe the runways, taxiways, airspace or weather conditions in the vicinity of the airport. Wind, altimeter and other weather information is usually extracted from the latest METAR or SPECI, and may not always be as representative of actual conditions as in AAS.

- b. *VAS*: the provision, via RCO, of information and advisories concerning the movements of vehicles, equipment and pedestrians on maneuvering areas at designated uncontrolled airports. VAS is provided at locations where RAAS is also provided. The flight service specialist will request vehicle traffic to leave the intended runway at least 5 minutes prior to the estimated time of landing but cannot ascertain visually if the traffic has actually vacated the runway.
- c. *Alerting service*: the notification of appropriate organizations regarding aircraft in need of SAR services or alerts of crash equipment, ambulances, doctors and any other safety services. Alerting of a responsible authority, if experiencing unlawful interference (hijack), bomb threat or inability to communicate in the clear, is also included in this service.
- d. *Emergency assistance service*: the provision of aid to a pilot when in an emergency, or potential emergency situation, such as being lost, encountering adverse weather conditions or experiencing aircraft-related emergencies or equipment failure. At some locations, emergency navigational assistance is provided to a pilot who is lost or experiencing IMC, by transferring the pilot to ATC for ATS surveillance service.
- e. *NOTAM Information Service*: the collection and dissemination of NOTAM, RSC and CRFI information by the flight service specialist. A pilot may report to a FIC or an FSS any hazards to the air navigation system that may need NOTAM distribution. The flight service specialist will distribute the information if it meets the criteria established in the Canadian NOTAM Operating Procedures (CNOP).
- f. *Weather observation service*: the observation, recording and dissemination of surface weather information for aviation purposes.

**CA 1
GENERAL****1.1.2.4 International Flight Service Station (IFSS)**

An aeronautical station that provides a communications service for international air operators. Gander is the only IFSS in Canada.

1.1.3 Arctic Territories

Arctic territories are serviced by the Edmonton (Alta.), Winnipeg (Man.), and Quebec (Que.) FICs, which provide FISE and emergency communication to aircraft operating in the Northwest Territories and Nunavut and in the vicinity of the ADIZ.

1.1.4 Military Flight Advisory Unit (MFAU)

DND operates Military Flight Advisory Unit (MFAU) which provide flight information services that enhance flight safety and efficiency. These services are available by calling the appropriate station followed by "Advisory", i.e., "Namao Advisory". MFAU provide enroute flight information, airport advisory, ground control, field condition reports, flight planning, alerting service, navigation assistance, NOTAM, PIREPs, and weather reports. An MFAU may be used to accept and relay VFR and IFR position reports and ATC clearances.

1.2 SERVICES OTHER THAN AIR TRAFFIC SERVICES (ATS)**1.2.1 Universal Communications**

A UNICOM is an air-to-ground communications facility operated by a private agency to provide Private Advisory Station (PAS) service at uncontrolled airports. At these locations the choice of frequencies are 122.7, 122.8, 123.0, 123.3, 123.5, 122.35, 122.95, 123.35, 122.725, 122.775 and 122.825 MHz.

The use of all information received from a UNICOM station is entirely at the discretion of the pilot. The frequencies are published in aeronautical information publications as a service to pilots, but Transport Canada takes no responsibility for the use made of a UNICOM frequency.

An AU is an air-ground communications service that can provide approach and landing information to IFR pilots. The service provider is required to ensure that:

- a. meteorological instruments used to provide the approach and landing information meet the requirements stipulated under CAR 804.01 (1)(c) or the applicable exemption; and
- b. UNICOM operators meet the training requirements stipulated under CAR 804.01(1)(c) or the applicable exemption.

Where the above standards are met, the AU operator may provide a station altimeter setting for an instrument procedure. The wind speed and direction for a straight-in landing from an instrument approach may or may not be provided.

Operators providing AU services may also advise pilots of the runway condition and of vehicles or aircraft positions on the maneuvering area.

**CA 1
GENERAL****1.2.2 Airport Radio/Community Aerodrome Radio Station**

Airport radio (APRT RDO), in most cases, is provided by a Community Aerodrome Radio Station (CARS) and has been established to provide aviation weather and communication services to enhance aircraft access to certain airports.

APRT RDO/CARS service is provided by observer-communicators (O/C) who are certified to conduct aviation weather observations and radio communications to facilitate aircraft arrivals and departures.

Hours of operation are listed in the AIRPORT DIRECTORY – CANADA.

Services provided by APRT RDO/CARS include the following:

a. Emergency Service

The O/C will respond to all emergency calls (distress, urgency and ELT signals), incidents or accidents by alerting a designated NAV CANADA FIC and appropriate local authorities.

b. Communication Service

The O/C will provide pilots with information in support of aircraft arrivals and departures, including wind, altimeter, runway and airport status (including vehicle intentions and runway condition), current weather conditions, PIREPs and known aircraft traffic.

NOTE 1: O/Cs are authorized to provide an altimeter setting for an instrument approach.

NOTE 2: O/Cs provide limited traffic information. APRT RDOs/CARS are located at uncontrolled airport within MF areas. Pilots must communicate on the MF as per uncontrolled airport procedures.

NOTE 3: O/Cs do not provide ATC services. At airports within controlled airspace served by APRT RDO/CARS, pilots must contact ATS via the RCO, PAL or telephone to obtain special VFR authorization or IFR clearances.

c. Weather Observation Service

The O/C will monitor, observe, record and relay surface weather data for aviation purposes (METARs or SPECIs) in accordance with CAR 804 standards. The O/C may request PIREPs from pilots to confirm weather conditions, such as height of cloud bases.

d. Flight Plan/flight Information Service

If necessary, at most APRT RDOs/CARS, O/Cs will accept flight plans/itineraries; however, pilots are encouraged to obtain a full preflight briefing and then file their flight plan/itinerary with an FIC.

NOTE: Pilots should be aware that O/Cs are only authorized to provide NOTAMs and weather information (METARs or SPECIs) for their own airport. Information for other areas/airports should be obtained from a FIC.

At APRT RDO/CARS sites collocated with an RCO, pilots should open and close flight plans/itineraries, pass position reports and obtain an enroute flight information services directly from the FIC via the RCO. At sites with no RCO, when requested by the pilot, the APRT

CA 1 GENERAL

RDO/CARS O/C will relay messages to open and close flight plans/itineraries and position reports (IFR, VFR, DVFR) to a FIC.

e. *Monitoring of Equipment/NAVAIDs*

During the APRT RDO/CARS hours of operation, O/Cs will monitor the status of equipment related to airport lighting, weather, communications, etc. Malfunctions will be reported to the designated NAV CANADA facility, and a NOTAM will be issued as required. For site-specific NAVAID monitoring by APRT RDO/CARS, refer to the enroute low altitude and enroute high altitude charts.

1.2.3 **Private Advisory Stations (PAS) — Controlled Airports**

Aeronautical operators may establish their own private facilities at controlled airports for use in connection with company business, such as servicing of aircraft, availability of fuel, and lodging. The use of PAS at controlled airports shall not include information relative to ATC, weather reports, condition of landing strips, or any other communication normally provided by ATC units.

1.2.4 **Apron Advisory Service**

Apron advisory service at most controlled airports is provided by ATS. However, some large airports are providing advisory service on aprons through a separate apron management unit staffed by airport or terminal operator personnel. This service normally includes gate assignment, push back instructions, and advisories on other aircraft and vehicles on the apron. Aircraft entering the apron will normally be instructed by the ground controller to contact APRON prior to or at the designated change-over point. Aircraft leaving the apron shall contact GROUND on the appropriate frequency to obtain taxi clearance prior to exiting the apron and before entering the maneuvering area.

1.3 **ATIS**

ATIS is the continuous broadcasting of recorded information for arriving and departing aircraft on a discrete VHF/UHF frequency. Its purpose is to improve controller and flight service specialist effectiveness and to relieve frequency congestion by automating the repetitive transmission of essential but routine information.

ATIS messages are recorded in a standard format and contain such information as:

- a. airport name and message code letter;
- b. weather information, including:
 1. time,
 2. surface wind, including gusts,
 3. visibility,
 4. weather and obstructions to vision,
 5. ceiling,
 6. sky condition,

**CA 1
GENERAL**

7. temperature,
 8. dew point,
 9. altimeter setting,
 10. pertinent SIGMETs, AIRMETs and PIREPs, and
 11. other pertinent remarks;
- c. type of instrument approach in use, including information on parallel or simultaneous converging runway operations;
 - d. landing runway, both IFR and VFR, including information on hold short operations and the stopping distance available;
 - e. departure runway, both IFR and VFR;
 - f. a NOTAM or an excerpt from a NOTAM, pertinent information regarding the serviceability of a NAVAID, or field conditions applicable to arriving or departing aircraft. These may be deleted from an ATIS message after a broadcast period of 12 hr at domestic airports or 24 hr at international airports;
 - g. instruction that aircraft are to acknowledge receipt of the ATIS broadcast on initial contact with ATC/FSS.

Each recording will be identified by a phonetic alphabet code letter, beginning with ALFA. Succeeding letters will be used for each subsequent message.

Example of an ATIS Message:

TORONTO INTERNATIONAL INFORMATION BRAVO. WEATHER AT ONE FOUR ZERO ZERO ZULU: WIND ZERO FIVE ZERO AT TWO ZERO, VISIBILITY FIVE HAZE, CEILING THREE THOUSAND OVERCAST, TEMPERATURE ONE EIGHT, DEW POINT ONE SIX, ALTIMETER TWO NINER FOUR SIX, PARALLEL ILS APPROACHES ARE IN PROGRESS. IFR LANDING ZERO SIX RIGHT, ZERO SIX LEFT. VFR LANDING ZERO SIX LEFT. DEPARTURE ZERO SIX LEFT. NOTAM: GLIDE PATH ILS RUNWAY ONE FIVE OUT OF SERVICE. INFORM ATC YOU HAVE INFORMATION BRAVO.

NOTE: Current time and RVR measurements will not be included in the ATIS message, but will be issued in accordance with current practices. Temperature and dew point information is derived only from the scheduled hourly weather observations.

Pilots hearing the broadcast should inform the ATC/FSS unit on initial contact that they have received the information, by repeating the code letter that identifies the message, thus obviating the need for the controller/specialist to issue information.

EXAMPLE:WITH BRAVO.

During periods of rapidly changing conditions that would create difficulties in keeping the ATIS message current, the following message will be recorded and broadcasted:

BECAUSE OF RAPIDLY CHANGING WEATHER/AIRPORT CONDITIONS, CONTACT ATC/FSS FOR CURRENT INFORMATION.

CA 1 GENERAL

The success and effectiveness of ATIS is largely dependent upon the cooperation and participation of airspace users; therefore, pilots are strongly urged to take full advantage of this service.

1.4 USE OF TERM “CAVOK”

The term “CAVOK” (KAV-OH-KAY) may be used in air-to-ground communications when transmitting meteorological information to arriving aircraft.

CAVOK refers to the simultaneous occurrence of the following meteorological conditions at an airport:

- a. no cloud below 5000 feet, or below the highest minimum sector altitude, whichever is higher, and no cumulonimbus;
- b. a visibility of 6 SM or more;
- c. no precipitation, thunderstorms, shallow fog, or low drifting snow.

This term, coupled with other elements of meteorological information, such as wind direction and speed, altimeter setting and pertinent remarks, will be used in transmissions directed to arriving aircraft and, where applicable, in the composition of ATIS messages. A pilot, on receipt of CAVOK, may request that detailed information be provided.

CAVOK does not apply to the provision of meteorological information to enroute aircraft and, therefore, will not be used when such information is transmitted to aircraft engaged in that particular phase of flight.

1.5 ATS SURVEILLANCE SERVICE

1.5.1 General

The use of ATS surveillance increases airspace utilization by allowing ATC to reduce the separation interval between aircraft. In addition, ATS surveillance permits an expansion of flight information services, such as ATS surveillance traffic information, ATS surveillance navigation assistance and information on chaff drops and bird activity. Due to limitations inherent in all ATS surveillance systems, it may not always be possible to detect aircraft, weather disturbances, etc. Where ATS surveillance information is derived from Secondary Surveillance Radar (SSR) only (i.e., without associated primary radar coverage), it is not possible to provide traffic information on aircraft that are not transponder-equipped or to provide some of the other flight information.

1.5.2 Procedures

Before providing ATS surveillance service, ATC will establish identification of the aircraft concerned either through the use of position reports, identifying turns, or the use of transponders. Pilots will be notified whenever identification is established, or lost.

EXAMPLE: IDENTIFIED; or IDENTIFICATION LOST.

Pilots are cautioned that identification of their flight does not relieve them of the responsibility for collision avoidance or terrain (obstacle) clearance. ATC will normally provide identified IFR and CVFR flights with information on observed targets. At locations where an SSR system is used

CA 1 GENERAL

without collocated primary radar equipment, ATC *cannot* provide traffic information on aircraft *without* a functioning transponder.

ATC assumes responsibility for terrain (obstacle) clearance when vectoring enroute IFR and CVFR flights and for IFR aircraft being vectored for arrival until the aircraft resumes normal navigation.

Vectors are used when necessary for separation purposes, when required by noise abatement procedures, when requested by the pilot, or whenever vectors will offer operational advantages to the pilot or the controller. When vectors are initiated, the pilot will be informed of the location to which the aircraft is being vectored.

EXAMPLE: VECTORS TO VICTOR THREE ZERO ZERO, TURN LEFT HEADING ZERO FIVE ZERO. VECTORS TO THE VANCOUVER V-O-R ZERO FIVE THREE RADIAL, FLY HEADING ZERO TWO ZERO. VECTORS TO FINAL APPROACH COURSE, DEPART KLEINBURG BEACON ON HEADING TWO FOUR ZERO.

Pilots will be informed when vectors are terminated, except when an arriving aircraft is vectored to the final approach course or to the traffic circuit.

EXAMPLE: RESUME NORMAL NAVIGATION.

When an aircraft is vectored to final approach or to the traffic circuit, the issuance of approach clearance indicates that normal navigation should be resumed.

Normally ATS surveillance service will be continued until an aircraft leaves the area of surveillance coverage, enters uncontrolled airspace, or is transferred to an ATC unit not equipped with ATS surveillance. When ATS surveillance service is terminated the pilot will be informed accordingly.

EXAMPLE: ATS SURVEILLANCE SERVICE TERMINATED.

1.5.3 Air Traffic Service (ATS) Surveillance Traffic Information

Traffic (or workload) permitting, ATC will provide IFR and CVFR flights with information on observed ATS surveillance targets whenever the traffic is likely to be of concern to the pilot, unless the pilot states that the information is not wanted. This information may be provided to VFR aircraft when requested by the pilot, depending on the classification of the airspace (see ATC — AIRSPACE REQUIREMENTS AND PROCEDURES — Airspace Classification).

When issuing ATS surveillance information, ATS units will frequently define the relative location of traffic, weather areas, etc., by referring to the clock position. In this system, the 12 o'clock position is based on the observed surveillance track rather than the actual nose of the aircraft. In conditions of strong crosswind, this can lead to a discrepancy between the position as reported by the controller and the position as observed by the pilot.

The following diagram illustrates the clock positions.

CA 1
GENERAL

Issue ATS surveillance traffic information to identified aircraft as follows:

- Position of the traffic in relation to the aircraft's observed track.
- Direction of flight.
- Type of aircraft, if known, or the relative speed, and the altitude if known.

NOTE: Direction of flight may be expressed as OPPOSITE DIRECTION or SAME DIRECTION, while the altitude may be expressed as a number of feet above or below the aircraft receiving the traffic information.

EXAMPLE: TRAFFIC, TWO O'CLOCK, THREE AND A HALF MILES, WESTBOUND, B747, ONE THOUSAND FEET ABOVE YOUR ALTITUDE.

Issue ATS surveillance traffic information to non-identified aircraft as follows:

- Position of the traffic in relation to a fix.
- Direction of flight.
- Type of aircraft, if known, or the relative speed, and the altitude if known.

NOTE: Direction of flight may be expressed as OPPOSITE DIRECTION or SAME DIRECTION, while the altitude may be expressed as a number of feet above or below the aircraft receiving the traffic information.

EXAMPLE: TRAFFIC, SEVEN MILES SOUTH OF RESOLUTE BAY VOR, NORTHBOUND, B737, FL300.

**CA 1
GENERAL****1.5.4 ATS Surveillance Navigation Assistance to Visual Flight Rules (VFR) Flights**

When requested by pilots, ATS surveillance-equipped ATC units will provide assistance to navigation in the form of position information, vectors or track, and ground speed checks. Flights requesting this assistance must be operating within areas of ATS surveillance and communication coverage, and be identified.

VFR flights may be provided with this service:

- a. at the request of a pilot, when traffic conditions permit;
- b. when the controller suggests and the pilot agrees; or
- c. in the interest of flight safety.

The pilot is responsible for avoiding other traffic and avoiding weather below VFR minima while on a VFR flight on vectors.

If a vector will lead a VFR flight into IFR weather conditions, the pilot must inform the controller and take the following action:

- a. if practicable, obtain a vector which will allow the flight to remain in VFR weather conditions; or
- b. if an alternative vector is not practicable, revert to navigation without assistance; or
- c. if the pilot has an IFR rating and the aircraft is equipped for IFR flight, he may file an IFR flight plan, and request an IFR clearance.

Emergency ATS surveillance assistance will be given to VFR flights which are able to maintain two-way radio communication with the unit, are within coverage, and can be identified.

Pilots requiring ATS surveillance assistance during emergency conditions should contact the nearest ATC unit and provide the following information:

- a. Declaration of emergency (state nature of difficulty and type of assistance required).
- b. Position of aircraft and weather conditions within which the flight is operating.
- c. Type of aircraft, altitude, and whether equipped for IFR flight.
- d. Whether pilot has an IFR Rating.

Pilots unable to contact ATS surveillance but in need of emergency assistance may alert ATS surveillance by flying a triangular pattern.

1.5.5 Obstacle Clearance During Vectors**a. IFR Flights**

The pilot of an IFR flight is responsible for ensuring that the aircraft is operated with adequate clearance from obstacles and terrain; however, when the flight is being vectored, ATC will ensure that the appropriate obstacle clearance is provided.

CA 1 GENERAL

Minimum vectoring altitudes (lower altitude at which an aircraft may be vectored and still meet obstacle clearance criteria), which may be lower than minimum altitudes shown on navigation and approach charts, have been established at a number of locations to facilitate transitions to instrument approach aids. When an IFR flight is cleared to descend to the lower altitude, ATC will provide terrain and obstacle clearance until the aircraft is in a position from which an approved instrument approach or a visual approach can be commenced.

If a communication failure occurs while a flight is being vectored at an altitude below the minimum IFR altitudes shown in the instrument approach chart, the pilot should climb immediately to the appropriate published minimum altitude, unless the flight is able to continue in Visual Meteorological Conditions (VMC).

b. *VFR Flights*

The pilot of a VFR aircraft remains responsible for maintaining adequate clearance from obstacles and terrain when the flight is being vectored by ATC.

If adequate obstacle or terrain clearance cannot be maintained on a vector, the pilot must inform the controller and take the following action:

1. if practicable, obtain a heading that will enable adequate clearance to be maintained, or climb to a suitable altitude; or
2. revert to navigation without ATS surveillance assistance.

1.5.6 **Misuse of Vectors**

Pilots have, on occasion, for practice purposes, followed ATS surveillance instructions issued to other pilots without realizing the potential hazard that accompanies such action.

ATC may require aircraft to make turns for identification; however, when more than one aircraft target is observed making a turn, identification becomes difficult or impossible. Should misidentification be the result of more than one aircraft following the instructions issued by ATC, it could be hazardous to the aircraft involved.

Any pilot wishing to obtain ATS surveillance practice, however, needs only to contact the appropriate ACC or TCU and request practice vectors. Practice vectors will be issued to the extent that air traffic conditions permit.

1.5.7 **Canadian Forces Radar Assistance**

The Canadian Forces can provide assistance in an emergency to civil aircraft operating within the Air Defence Identification Zone (ADIZ).

No responsibility for the direct control of aircraft is accepted and radar assistance does not absolve the captain of the responsibility of complying with ATC clearances or other required procedures. Assistance consists of:

- a. track and ground speed checks (speeds in KT);
- b. position of the aircraft in geographic reference, or by bearing and distance from the station (distances are in NM and bearings in degrees True);

CA 1 GENERAL

- c. position of heavy cloud in relation to the aircraft.

To obtain assistance in the NWS Area, call “Radar Assistance” on 126.7 MHZ or when circumstances require a MAYDAY call, use 121.5 MHZ, giving all the details necessary. When assistance is required in ADIZ areas contact will have to be made on the 121.5 MHZ frequency or on the UHF frequencies 243.0 MHZ or 364.2 MHZ. Initial contact should be made at the highest practicable altitude. If air defence commitments preclude the granting of radar assistance, the ground station will transmit the word “UNABLE” and no further explanation will be given.

1.5.8 The Use of ATS Surveillance in the Provision of Aerodrome Advisory Service (AAS) and Remote Aerodrome Advisory Service (RAAS) by Flight Service Stations (FSS)

Certain FSSs are equipped with an ATS surveillance display to aid the flight service specialist in monitoring the aircraft traffic situation and to enhance the accuracy of traffic information provided in AAS or RAAS.

An FSS equipped with an ATS surveillance display:

- a. may instruct an aircraft to “SQUAWK IDENT” or assign a specific SSR code to the aircraft;
- b. will acknowledge the squawk transmission or SSR code change by stating the phrase “ROGER IDENT”;
- c. will issue the reminder “NO CONTROL SERVICE AVAILABLE, THIS IS AN ADVISORY SERVICE,” if deemed appropriate;
- d. may issue observed ATS surveillance traffic information with reference to the 12-hr clock position or geographical locations.

It is important for pilots to keep in mind that:

- a. flight service specialists may stop monitoring the ATS surveillance display at any time without prior notice to aircraft;
- b. FSSs do not inform aircraft when identification is lost;
- c. FSSs do not provide control services such as vectors and conflict resolution;
- d. pilots are responsible for maintaining a visual lookout outside the cockpit at all times for the purpose of avoiding a collision with other aircraft, terrain and obstacles.

1.6 ATC CLEARANCES, INSTRUCTIONS AND INFORMATION

Whenever pilots receive and accept an ATC clearance, they shall comply with the clearance. If unable to comply with the clearance, pilots should immediately inform ATC of this fact, since acknowledgment of the clearance alone will be taken by a controller as indicating acceptance. For example, upon receiving a clearance for takeoff, pilots should acknowledge the clearance and take off without undue delay or, if not ready to take off at that particular time, inform ATC of his or her intentions, in which case the clearance may be changed or cancelled.

A clearance will be identified by the use of some form of the word “clear” in its contents. An instruction will always be worded in such a manner as to be readily identified, although the word

CA 1 GENERAL

“instruct” will seldom be included. Pilots shall comply with and acknowledge receipt of all ATC instructions directed to and received by them, provided the safety of the aircraft is not jeopardized (CAR 602.31).

CAR 602.31 permits pilots to deviate from an ATC instruction or clearance in order to follow TCAS or ACAS RAs. Pilots responding to an RA shall advise the appropriate ATC unit of the deviation as soon as practicable and shall expeditiously return to the last ATC clearance received and accepted, or the last ATC instruction received and acknowledged prior to the RA maneuver. Aircraft maneuvers conducted during an RA should be kept to the minimum necessary to satisfy the resolution advisory. For more information on TCAS and ACAS, see ATC paragraph 12.16.

ATC is not responsible for the provision of IFR separation to an IFR aircraft which carries out a TCAS or ACAS RA maneuver until one of the following conditions exist:

- a. the aircraft has returned to the last ATC clearance received and accepted, or last ATC instruction received and acknowledged prior to the RA; or
- b. an alternate ATC clearance or instruction has been issued.

TCAS and ACAS do not alter or diminish the pilot-in-command's responsibility to ensure safe flight. Since TCAS and ACAS do not respond to aircraft which are not transponder-equipped or to aircraft with a transponder failure, TCAS and ACAS alone do not ensure safe operation in every case. The services provided by ATC units are not predicated upon the availability of TCAS or ACAS equipment in an aircraft.

It should be remembered that control is predicated on known air traffic only and, when complying with clearances or instructions, pilots are not relieved of the responsibility for practicing good airmanship.

NOTE: A clearance or instruction is only valid while in controlled airspace. Pilots crossing between controlled and uncontrolled airspace should pay close attention to the terrain and obstacle clearance requirements.

ATS personnel routinely inform pilots of conditions, observed by others or by themselves, which may affect flight safety and are beyond their control. Examples of such conditions are observed airframe icing and bird activity. These are meant solely as assistance or reminders to pilots and are not intended in any way to absolve the pilot of the responsibility for the safety of the flight.

1.6.1 Inability to Issue Clearance

ATC clearances are based on known traffic conditions and airport limitations which affect the safety of aircraft operations. This encompasses aircraft in flight and on the maneuvering area, vehicles, and other potential obstructions. ATC is not authorized to issue ATC clearances when traffic conditions are unknown, when any part of the airport is partially or fully closed, or when the airport or runway operating minima are not met.

There are two distinct phrases used when unable to issue ATC clearances:

- a. **AT YOUR DISCRETION** — Used to approve aircraft movement on any surface not visible from the control tower due to a physical obstruction other than weather phenomena, or on the non-maneuvering area. Pilots are responsible for maneuvering safely with respect to traf-

CA 1 GENERAL

fic or hazards encountered during the operation. ATC will provide information on known traffic or obstructions when possible.

- b. **UNABLE TO ISSUE CLEARANCE** — Used when controllers are not authorized to issue an ATC clearance. Pilots who continue without a clearance in these circumstances may be subject to regulatory action by TC. ATC will provide pertinent taxi, take-off or landing information and then file an aviation occurrence report. Pilots are responsible for maneuvering safely with respect to traffic or other hazards encountered during the operation.

1.6.1.1 *Examples*

The following are scenarios in which ATC may not be able to provide a clearance, followed by ensuing ATC actions, and examples of phraseology that will be used.

- a. **ATIS message** — ATC will include the following information in an ATIS message, as applicable, upon restriction or suspension of landings or takeoffs. These restrictions or suspensions may be due to the implementation of RVOP or LVOP, direction from the airport operator, obstructed runway protected area, or other reasons.

NOTE: When conditions are rapidly changing, this information may be issued by ATC, rather than via the ATIS.

EXAMPLE: LOW VISIBILITY PROCEDURES IN EFFECT. RUNWAY ZERO FOUR NOT AUTHORIZED FOR LANDING.

REDUCED VISIBILITY PROCEDURES IN EFFECT. RUNWAY TWO TWO NOT AVAILABLE.

RUNWAY ONE THREE NOT AVAILABLE DUE TO RUNWAY PROTECTED AREA OBSTRUCTION.

- b. *Operations on a surface other than a runway*

- 1. If the pilot of a fixed-wing aircraft requests landing or takeoff from a surface other than a runway or area approved and designated for that purpose, ATC will provide traffic and obstruction information; control instructions, if necessary; and inform the pilot that landing or takeoff will be at the pilot's discretion.

NOTE: Examples of surfaces other than a runway may include areas at or adjacent to the airport, areas in the control zone but not at the airport, a water airport, or a temporary landing area in the control zone.

EXAMPLE: GOLF JULIETT ALFA LIMA, WIND THREE ZERO ZERO AT FIFTEEN, TAKE OFF AT YOUR DISCRETION.

- 2. Workload permitting, ATC will provide traffic and obstruction information to aircraft taxiing on a non-maneuvering area.

EXAMPLE: GOLF LIMA BRAVO JULIETT, TAXI AT YOUR DISCRETION.

- 3. If necessary, ATC will inform a taxiing aircraft that a portion of the maneuvering area is not visible from the tower and, if possible, provide traffic and obstruction information.

CA 1 GENERAL

NOTE: Restricted visibility of the maneuvering area may be the result of a structure, but excludes situations due to weather.

EXAMPLE: FOXTROT ALFA BRAVO CHARLIE, TAXIWAY NOT VISIBLE, TAXI AT YOUR DISCRETION ON TAXIWAY ALFA.

- c. *RVOP and LVOP* — The following procedures will be used by ATC when implementation of RVOP or LVOP results in maneuvering area restrictions or closures. RVOP and LVOP procedures vary across Canada, depending on airport operating limits.

1. If a pilot requests taxi clearance, ATC will inform the pilot that taxi clearance cannot be issued, and provide the reason. Pilots shall make the request prior to commencing push-back with the intent of taking off; commencing push-back with the intent of taxiing to the de-icing bay; or commencing taxiing on the maneuvering area under the aircraft's own power with the intent of taking off.

EXAMPLE: FOXTROT BRAVO WHISKY DELTA, UNABLE TAXI CLEARANCE ON TAXIWAY CHARLIE, LOW VISIBILITY PROCEDURES IN EFFECT.

2. If a pilot is taxiing for takeoff, ATC will inform the pilot that clearance cannot be issued on the intended runway; provide the reason; determine if another runway is available for takeoff; inform the pilot of the alternate runway; and request the pilot's intentions.

EXAMPLE: GOLF JULIETT ALFA LIMA, UNABLE CLEARANCE. REDUCED VISIBILITY PROCEDURES IN EFFECT. RUNWAY THREE TWO CLOSED.

Then, if appropriate:

GOLF JULIETT ALFA LIMA, RUNWAY TWO FIVE AVAILABLE, ADVISE INTENTIONS.

NOTE: If no alternate runway is available ATC will request the pilot's intentions.

EXAMPLE: FOXTROT ALFA BRAVO CHARLIE, UNABLE CLEARANCE. LOW VISIBILITY PROCEDURES IN EFFECT. ALL RUNWAYS CLOSED. ADVISE INTENTIONS.

3. If a pilot requests taxi after landing, ATC will provide taxi clearance.

EXAMPLE: FOXTROT BRAVO WHISKY DELTA, TAXI VIA ECHO.

4. If a pilot requests landing or takeoff, ATC will inform the pilot that a clearance cannot be issued; provide the reason; and request the pilot's intentions.

EXAMPLE: GOLF JULIETT ALFA LIMA, UNABLE CLEARANCE RUNWAY ONE EIGHT, LANDING NOT AUTHORIZED. ADVISE INTENTIONS.

5. If the pilot chooses to land or take off anyway, and traffic permits, ATC will acknowledge the pilot's intentions; provide landing or take-off information as well as any special information required; notify the airport operator; and complete an aviation occurrence report.

NOTE: Special information may include traffic, hazards, obstructions, runway exits, runway surface conditions, or other pertinent information.

EXAMPLE: GOLF LIMA BRAVO JULIETT, ROGER.

CA 1 GENERAL

- d. *Denial of clearance* — The following procedures will be used when ATC refuses a clearance request because the airport or part of the airport is closed by the operator; or ATC is directed to deny taxi clearance by NAV CANADA or other authority.

1. If the pilot requests a landing, takeoff or other maneuver, ATC will inform the pilot that a clearance cannot be issued; provide the reason; provide pertinent NOTAM(s) or airport condition directive(s); and request the pilot's intentions.

EXAMPLE: WESTJET THREE SEVEN ONE, UNABLE CLEARANCE. RUNWAY ZERO SEVEN IS CLOSED FOR MAINTENANCE UNTIL ONE NINE ZERO ZERO ZULU AS PER NOTAM. ADVISE INTENTIONS.

2. If the pilot chooses to land, take off or maneuver anyway, and traffic permits, ATC will acknowledge the pilot's intentions; provide landing, take-off or maneuvering information as well as any special information required; notify the airport operator; and complete an aviation occurrence report.

NOTE: Special information may include traffic, hazards, obstructions, runway exit, runway surface conditions, or other pertinent information.

EXAMPLE: AIR CANADA THREE FIVE SIX, ROGER.

- e. *Taxi authorization* — If a pilot requests a push-back from a loading position on the apron, ATC will inform the pilot that the push-back is at pilot's discretion and provide traffic information, if possible.

EXAMPLE: NOVEMBER ONE THREE SIX TWO ALFA, PUSH BACK AT YOUR DISCRETION.

- f. *Helicopters* — If a helicopter pilot intends to land or take off from a non-maneuvering area approved for that purpose, ATC will provide traffic and obstruction information; control instructions, if necessary; and inform the pilot that landing or takeoff will be at the pilot's discretion.

EXAMPLE: GOLF JULIETT ALFA DELTA, TRAFFIC CHEROKEE DEPARTING RUNWAY THREE ONE, WIND THREE ZERO ZERO AT TEN. TAKE OFF AT YOUR DISCRETION FROM APRON FOUR.

- g. *Taxiing aircraft and ground traffic* — The following procedures will be used when ATC is unable to determine that the runway or runway protected area is or will be free of obstacles before either an arrival crosses the threshold or a departure starts its take-off roll.

NOTE: Obstacles include taxiing aircraft and ground traffic.

1. If the pilot requests a landing or takeoff, ATC will inform the pilot that a clearance cannot be issued; provide the reason; and request the pilot's intentions.

EXAMPLE: GOLF ZULU YANKEY ZULU, UNABLE LANDING CLEARANCE RUNWAY ONE FOUR, VEHICLE INSIDE THE RUNWAY PROTECTED AREA AT ALFA. ADVISE INTENTIONS.

CA 1 GENERAL

2. If the pilot chooses to land or take off anyway, and traffic permits, ATC will acknowledge the pilot's intentions; provide landing or take-off information as well as any special information required; notify the airport operator; and complete an aviation occurrence report.

NOTE: Special information may include traffic, hazards, obstructions, runway exit, runway surface conditions or other pertinent information.

EXAMPLE: JAZZ SIX EIGHT EIGHT, ROGER.

3. If a landing or take-off clearance has been issued and ATC is unable to determine that the runway or runway protected area is or will be free of obstacles before an arrival crosses the threshold, or a departure starts its take-off roll, ATC will cancel the clearance.

NOTE: Controllers will use their best judgement if cancelling the clearance may result in a hazardous situation.

EXAMPLE: GOLF ALFA DELTA ALFA, TAKE-OFF CLEARANCE CANCELLED, AIRCRAFT INSIDE THE RUNWAY PROTECTED AREA AT CHARLIE, ADVISE INTENTIONS.

1.7 AIR TRAFFIC CONTROL (ATC) SERVICE PRIORITY

1.7.1 Normal Conditions

Normally, ATC provides control service on a first-come, first-served basis. However, controllers may adjust the arrival or departure sequence in order to facilitate the maximum number of aircraft movements with the least average delay. Altitude assignment may also be adjusted in order to accommodate the maximum number of aircraft at their preferred altitudes, or to comply with ATFM requirements.

1.7.2 Special Conditions

Flight priority is provided to:

- a. an aircraft that is known or believed to be in a state of emergency;

NOTE: This category includes aircraft subjected to unlawful interference, or other distress or urgency conditions that may compel the aircraft to land or require flight priority.

- b. a MEDEVAC flight;
- c. military or civilian aircraft participating in SAR missions and identified by the radiotelephony call sign "RESCUE" and the designator "RSCU," followed by an appropriate flight number;
- d. military aircraft that are departing on:
 1. operational air defence flights,
 2. planned and coordinated air defence training exercises; and
 3. exercises to an altitude reservation; or
- e. an aircraft carrying Her Majesty the Queen, the Governor General, the Prime Minister, heads of state, or foreign heads of government.

**CA 1
GENERAL****1.7.3 Minimum Fuel Advisory**

Pilots may experience situations where traffic, weather or other delays result in concern about the aircraft's fuel state. The term MINIMUM FUEL describes a situation where the aircraft's fuel supply has reached a state where the flight is committed to land at a specific airport and no additional delay can be accepted. The pilot should advise ATC as soon as possible that a MINIMUM FUEL condition exists. This is not an emergency situation, but merely an advisory that indicates an emergency is possible should any undue delay occur.

A minimum fuel advisory does not imply an ATC traffic priority; however, ATC special flight handling procedures are as follows:

- a. Be alert for any occurrence or situation that might delay the aircraft;
- b. Respond to the declaration and keep the pilot informed of any anticipated delay as soon as you become aware, using the following phraseology:

ROGER or

ROGER NO DELAY EXPECTED or

ROGER EXPECT (delay information).

- c. Inform the next sector or unit of the minimum fuel status of the aircraft and
- d. Record the information in the unit log, reduce unnecessary radio transmissions and ensure appropriate responses; use of internationally recognized fuel-related phraseology among pilots and controllers is essential.

Traffic priority is given to a pilot who declares an emergency for fuel by broadcasting MAYDAY MAYDAY MAYDAY FUEL. Use of standardized pilot phraseology distinguishes minimum fuel from a fuel emergency, assuring pilot intent without further verification.

1.8 TRANSPONDER OPERATION**1.8.1 General**

Transponders substantially increase the capability of radar to detect aircraft. The use of automatic pressure altitude reporting equipment (Mode C) enables controllers to quickly determine where potential conflicts could occur. Proper transponder operating procedures and techniques will provide both VFR and IFR aircraft with a higher degree of safety. In addition, proper usage of transponders with Mode C capability results in reduced communications and more efficient service.

When pilots receive ATC instructions concerning transponder operation, they shall operate transponders as directed until they receive further instructions or until the aircraft has landed, except in an emergency, communication failure or act of unlawful interference.

ATC radar units are equipped with alarm systems that respond when the aircraft is within radar coverage and the pilot selects the emergency, communication failure, or act of unlawful interference transponder code. It is possible to unintentionally select these codes momentarily when changing the transponder from one code to another. To prevent unnecessary activation of the alarm, pilots should avoid inadvertent selection of 7500, 7600 or 7700 when changing the code, if either of the first two digits to be selected is a seven. For example, if it is necessary to change

CA 1 GENERAL

from code 1700 to code 7100, first change to code 1100, then code 7100, NOT code 7700 and then code 7100. Do not select “STANDBY” while changing codes as this will cause the target to be lost on the ATC radar screen.

Pilots should adjust transponders to “STANDBY” while taxiing for takeoff, to “ON” (or “NORMAL”) as late as practicable before takeoff, and to “STANDBY” or “OFF” as soon as practicable after landing. In practice, transponders should be turned on only upon entering the active runway for departure and turned off as soon as the aircraft exits the runway after landing. Some airports have implemented surface surveillance services using multilateration (MLAT). MLAT relies on transponder returns; therefore, pilots of transponder equipped aircraft should leave their transponders in the transmit mode at all times when on the airfield. Pilots should ensure that the transponder code issued by ATC is selected before switching the transponder out of “STANDBY”. In the event that no code has been issued by ATC, transponder code 1000 should be selected.

In the event of a transponder or automatic pressure altitude reporting equipment (Mode C) failure during a flight when its use is mandatory, an aircraft may be operated to the next airport of intended landing; it may, thereafter, complete an itinerary or go to a repair base, if authorized by ATC.

ATC may, upon receiving a written request, authorize an aircraft not equipped with a functioning transponder or Mode C to operate in airspace where its use is mandatory. The purpose of this advanced request is to enable ATC to determine if the operation of the aircraft can be handled in the airspace at the time requested without compromising the safety of air traffic. Approval may be subject to such conditions and limitations deemed necessary to preserve safety. Pilots must obtain approval before entering airspace where it is mandatory to be equipped with a functioning transponder and automatic pressure altitude reporting equipment. This includes aircraft proposing to take off from an airport located within that airspace.

1.8.2 Transponder Requirements

CAR 605.35 outlines the transponder operating rule, as well as the circumstance in which operation with an unserviceable transponder is permitted. It also outlines the procedures to follow in order to operate an aircraft within transponder airspace without being equipped with a transponder and automatic pressure-altitude reporting equipment. CAR 601.03 states that transponder airspace consists of:

- a. All Class A, B and C airspace as specified in the *Designated Airspace Handbook*; and
- b. any Class D or E airspace specified as transponder airspace in the *Designated Airspace Handbook*.

This includes all Class E airspace extending upwards from 10,000 ft ASL up to and including 12,500 ft ASL within radar coverage, as shown in Figure 1.1.

Pilots of IFR aircraft operating within controlled or uncontrolled high-level airspace should adjust their transponder to reply on Mode A, Code 2000 and on Mode C, unless otherwise instructed by ATC.

NOTE: Pilots instructed to squawk a discrete code should not adjust their assigned transponder code when informed that radar or surveillance service is terminated. The termination of radar or surveillance service does not necessarily constitute direction to change to Code 2000.

CA 1
GENERAL

Figure 1.1 — Transponder Airspace

1.8.3 IFR Operations in Other Low Level Airspace

During IFR flight in controlled low level airspace other than that described earlier, adjust your transponder to reply on Mode A, Code 1000 and on Mode C (if available) unless otherwise instructed by ATC. If an IFR flight plan is cancelled or changed to a VFR flight plan, the trans-

CA 1 GENERAL

ponder should be adjusted to reply on the appropriate VFR code, as specified in the following paragraphs, unless otherwise instructed by ATC.

To enhance the safety of IFR flight in uncontrolled low level airspace, pilots are encouraged to adjust their transponders to reply on Mode A, Code 1000, plus Mode C (if available), unless otherwise instructed by ATC.

1.8.4 VFR Operations

During VFR flight in low level airspace, adjust your transponder to reply on the following unless otherwise assigned by an ATS unit:

- a. Mode A, Code 1200, for operation at or below 12,500 feet ASL;
- b. Mode A, Code 1400, for operation above 12,500 feet ASL.

Upon leaving the confines of an airspace for which a special code assignment has been received, the pilot is responsible for changing to the code shown in (a) or (b) above, unless assigned a new code by an ATS unit.

NOTE: When climbing above 12,500 feet ASL, VFR pilots should use Code 1200 until they leave 12,500 feet ASL, then select Code 1400. When descending from above 12,500 feet ASL, VFR pilots should select Code 1200 upon reaching 12,500 feet ASL. Pilots of aircraft equipped with a transponder capable of Mode C automatic altitude reporting should adjust their transponder to reply on Mode C when operating in Canadian airspace unless otherwise instructed by an ATS unit.

Pilots of gliders that are equipped with a transponder should adjust the transponder to reply on Mode A, Code 1202 at all times, unless otherwise directed by air traffic control (ATC). If their transponder is capable, pilots should use Mode C as well.

1.8.5 Phraseology

ATS personnel will use the following phraseology when referring to transponder operation:

SQUAWK (code) — Operate transponder on designated code in Mode A.

SQUAWK IDENT — Engage the “IDENT” feature of the transponder.

NOTE: A pilot should operate the identification (“IDENT”) feature only when requested by an ATS unit.

SQUAWK MODE CHARLIE — Activate Mode C with automatic altitude reporting.

STOP SQUAWK MODE CHARLIE — Turn off automatic altitude reporting function.

RESET TRANSPONDER — Reset your transponder, and transmit the SQUAWK (code) currently assigned. This phraseology may be used if the target or identity tag data is not being displayed as expected.

REPORT YOUR ALTITUDE — This phraseology may be used when it is necessary to validate altitude readouts by comparing the readouts value with an altitude reported by the aircraft. An altitude readout is considered valid if the readout value does not differ from the aircraft-reported altitude by more than 200 feet, and invalid if the difference is 300 feet, or more.

**CA 1
GENERAL**

NOTE: Readout values are displayed in 100-foot increments.

SQUAWK STANDBY – SQUAWK (code) — The Present Position Symbol (PPS) disappears or changes to a Primary Surveillance Radar (PSR) symbol after the aircraft is instructed to change its transponder to STANDBY; the PPS reappears or changes back to a Secondary Surveillance Radar (SSR) symbol after the aircraft is requested to return the transponder to normal operation.

1.8.6 Emergencies

In the event of an emergency, and if unable to establish communication immediately with an ATC unit, a pilot wishing to alert ATC to the emergency situation should adjust the transponder to reply on Code 7700. Thereafter, communication should be established with ATC as soon as possible, and the transponder should be operated as directed by ATC.

1.8.7 Communication Failure

In the event of a communication failure, the pilot should adjust the transponder to reply on Code 7600 to alert ATC to the situation. This does not relieve the pilot of the requirement to comply with the appropriate communications failure procedures for IFR flight.

1.8.8 Unlawful Interference

Canada, along with other nations, has adopted a special SSR transponder code (7500) for use by pilots whose aircraft are hijacked. ATC does not assign this code unless the pilot informs ATC of an act of unlawful interference in progress.

Selection of the code activates an alarm system and points out the aircraft on radar displays. If the controller doubts that an aircraft is the subject of an act of unlawful interference (as could occur when a code change was requested and the act of unlawful interference code appeared rather than the assigned code), the controller will say, CONFIRM SQUAWK SEVEN FIVE ZERO ZERO. If the pilot answers yes, the controller will alert the ATC system. If the pilot replies no, the controller will reassign the proper code. If the pilot does not reply, the controller will take this as confirmation that the use of code 7500 is intentional. If after using code 7500 an aircraft changes to Code 7700, or transmits a message including the phrase TRANSPONDER SEVEN SEVEN ZERO ZERO, it indicates that the aircraft is threatened by grave and imminent danger and requires immediate assistance.

1.9 COLLISION AVOIDANCE — RIGHT OF WAY (CARs)**Reckless or Negligent Operation of Aircraft****CAR 602.01**

No person shall operate an aircraft in such a reckless or negligent manner as to endanger or be likely to endanger the life or property of any person.

Right-of-Way — General**CAR 602.19**

- (1) Notwithstanding any other provision of this section,

**CA 1
GENERAL**

- (a) the pilot-in-command of an aircraft that has the right-of-way shall, if there is any risk of collision, take such action as is necessary to avoid collision; and
 - (b) where the pilot-in-command of an aircraft is aware that another aircraft is in an emergency situation, the pilot-in-command shall give way to that other aircraft.
- (2) When two aircraft are converging at approximately the same altitude, the pilot-in-command of the aircraft that has the other on its right shall give way, except as follows:
 - (a) a power-driven, heavier-than-air aircraft shall give way to airships, gliders and balloons;
 - (b) an airship shall give way to gliders and balloons;
 - (c) a glider shall give way to balloons; and
 - (d) a power-driven aircraft shall give way to aircraft that are seen to be towing gliders other objects or carrying a slung load.
- (3) When two balloons operating at different altitudes are converging, the pilot-in-command of the balloon at the higher altitude shall give way to the balloon at the lower altitude.
- (4) Where an aircraft is required to give way to another aircraft, the pilot-in-command of the first-mentioned aircraft shall not pass over or under, or cross ahead of, the other aircraft unless passing or crossing at such a distance as will not create any risk of collision.
- (5) Where two aircraft are approaching head-on or approximately so and there is a risk of collision, the pilot-in-command of each aircraft shall alter its heading to the right.
- (6) An aircraft that is being overtaken has the right-of-way and the pilot-in-command of the overtaking aircraft, whether climbing, descending or in level flight, shall give way to the other aircraft by altering the heading of the overtaking aircraft to the right, and no subsequent change in the relative positions of the tow aircraft shall absolve the pilot-in-command of the overtaking aircraft from this obligation until that aircraft has entirely passed and is clear of the other aircraft.
- (7) Where an aircraft is in flight or maneuvering on the surface, the pilot-in-command of the aircraft shall give way to an aircraft that is landing or about to land.
- (8) The pilot-in-command of an aircraft that is approaching an airport for the purpose of landing shall give way to any aircraft at a lower altitude that is also approaching the airport for the purpose of landing.
- (9) The pilot-in-command of an aircraft at a lower altitude, as described in subsection (8), shall not overtake or cut in front of an aircraft at a higher altitude that is in the final stages of an approach to land.
- (10) No person shall conduct or attempt to conduct a takeoff or landing in an aircraft until there is no apparent risk of collision with any aircraft, person, vessel, vehicle or structure in the take-off or landing path.

**CA 1
GENERAL****Right-of-Way — Aircraft Maneuvering on Water***CAR 602.20*

- (1) Where an aircraft on the water has another aircraft or a vessel on its right, the pilot-in-command of the first-mentioned aircraft shall give way.
- (2) Where an aircraft on the water is approaching another aircraft or a vessel head-on, or approximately so, the pilot-in-command or first-mentioned aircraft shall alter its heading to the right.
- (3) The pilot-in-command of an aircraft that is overtaking another aircraft or a vessel on the water shall alter its heading to keep well clear of the other aircraft or the vessel.

Avoidance of Collision*CAR 602.21*

No person shall operate an aircraft in such proximity to another aircraft as to create a risk of collision.

Formation Flight*CAR 602.24*

No person shall operate an aircraft in formation with other aircraft except by pre-arrangement between

- (a) the pilots-in-command of the aircraft; or
- (b) where the flight is conducted within a control zone, the pilot-in-command and the appropriate air traffic control unit.

1.10 AEROBATIC FLIGHT (CARs 602.27 and 602.28)**Aerobatic Maneuvers — Prohibited Areas and Flight Conditions***CAR 602.27*

No person operating an aircraft shall conduct aerobatic maneuvers

- (a) over a built-up area or an open-air assembly of persons;
- (b) [Repealed, SOR/2019-119, s. 28]
- (c) when flight visibility is less than three miles;
- (d) below 2000 ft AGL, except in accordance with a special flight operations certificate issued pursuant to Section 603.02 or 603.67;
- (e) in any class of airspace that requires radio contact with air traffic services unless the appropriate unit that provides air traffic services is advised that aerobatic maneuvers will be conducted; or

**CA 1
GENERAL**

- (f) in Class A, B or C airspace or Class D Control Zones without prior coordination between the pilot-in-command and the air traffic control unit that provides air traffic control service in that airspace.

Aerobatic Maneuvers with Passengers*CAR 602.28*

No person operating an aircraft with a passenger on board shall conduct aerobatic maneuvers unless the pilot-in-command of the aircraft has engaged in

- (a) at least 10 hours dual flight instruction in the conducting of aerobatic maneuvers or 20 hours conducting aerobatic maneuvers; and
- (b) at least one hour of conducting aerobatic maneuvers in the preceding six months.

1.11 PILOT REPORTS**1.11.1 General**

Pilots are requested to make the following reports in the interests of national security, meteorite research and forest fire and pollution control.

1.11.2 CIRVIS Reports — Vital Intelligence Sightings

Communication Instructions for Reporting Vital Intelligence Sightings (CIRVIS) reports should be made immediately upon a vital intelligence sighting of any airborne and ground objects or activities that appear to be hostile, suspicious, unidentified or engaged in possible illegal smuggling activity.

Examples of events requiring CIRVIS reports are: unidentified flying objects, submarines, or surface warships identified as being non-Canadian or non-American; violent explosions; unexplained or unusual activity, including the presence of unidentified or suspicious ground parties in Polar regions, at abandoned airstrips or other remote, sparsely populated areas.

These reports should be made to the nearest Canadian or U.S. government FIC or ATC unit.

A report via air/ground communications should include the words “CIRVIS CIRVIS CIRVIS”, followed by:

- a. the identification of the reporting aircraft;
- b. a brief description of the sighting (number, size, shape, etc.);
- c. the position of the sighted object or activity;
- d. the date and time of sighting in UTC;
- e. the altitude of the object;
- f. the direction of movement of the object;
- g. the speed of the object; and
- h. any identification.

**CA 1
GENERAL****1.11.3 Fire Detection — Northern Areas**

Indigenous and Northern Affairs Canada (INAC) has requested the cooperation of all persons connected with aviation in the prevention, detection and suppression of fires in the northern areas of Canada.

Reports should be made to the nearest ATS Unit immediately upon sighting and include:

- a. location of the fire;
- b. approximate size of the fire;
- c. color of the smoke; and
- d. direction of the smoke.

This information will assist fire crews in getting to fires with minimum delay and with the right type of equipment.

1.11.4 Pollution Reports

Any aircraft, upon sighting any vessel discharging pollutants (oil) in Canadian waters, Fishing Zones or Arctic Shipping Control Zones should inform the nearest ATS unit.

The pollution report should include the following information:

- a. Name of air operator or aircraft owner;
- b. Pilot's name;
- c. Destination of aircraft;
- d. Aircraft's identification;
- e. Date and time of sighting;
- f. Heading of vessel and name, port of registry and type (if possible);
- g. Latitude and longitude of sighting;
- h. Type and extent of pollution;
- i. Current and wind direction (if possible); and
- j. Sea state (height of waves, if possible).

The ATS unit will forward any pollution reports to the Coast Guard Marine Communications and Traffic Services (MCTS) Centre. For more information refer to their website:

<https://www.ccg-gcc.gc.ca/contact/emergency-urgence/marine-pollution-marine-eng.html>

1.12 ATS REPORTS

Under current regulation, ATS units are required to report to the Minister of Transport any aviation occurrence that may contravene the CARs.

Any investigation of the circumstances or subsequent decision on whether a breach has taken place is the responsibility of TC. Any necessary follow-up action will be conducted by TC Civil Aviation regulatory authorities.

CA 1 GENERAL

1.13 CONSERVATION

1.13.1 Fur and Poultry Farms

Experience has shown that aviation noise caused by rotary wing and fixed wing aircraft flying at low altitudes can cause serious economic losses to the farming industry. The classes of livestock particularly sensitive are poultry (including ostriches and emus), because of the crowding syndrome and stampeding behavior they exhibit when irritated and frightened, and foxes who, when excited, will eat or abandon their young. Avoid overflying these farms below 2000 feet AGL.

Fur farms display watch towers or 20 foot high pylons painted chrome yellow and black, with a red flag flying from a low mast during the months of February, March, April and May, that should be avoided below 2000 feet AGL.

Pilots are, therefore, warned that any locations so marked should be avoided and that during the months of February, March, April and May, special vigilance should be maintained.

1.13.2 Protection of Wildlife

It is vital that all pilots understand the importance of wildlife conservation. They are urged to become familiar with the game laws in force in the various provinces and territories, and encouraged to cooperate with all game officers to ensure that violations of game laws do not occur. The *Migratory Birds Regulations* prohibit the intentional killing of migratory birds through the use of an aircraft.

Pilots should be aware that flying low over herds of reindeer, caribou, moose or muskoxen may result in reducing the animal population. Accidents resulting in broken bones may increase. Exhausted and disorganized animals are more susceptible to be attacked by wolves; feeding is interrupted; and normal herd movement and reproductive functions may be seriously disrupted.

Serious damage can also be done to migratory birds due to low flying aircraft. The migratory bird regulations prohibit the killing of game birds through the use of an aircraft. Geese particularly are in great fear of aircraft; and their movements may be seriously disorganized by such interference. These geese are a valuable asset to Canada. As several species are nearing extinction, it is felt that every effort should be made to preserve them.

In the interest of conserving wildlife, pilots must not fly at an altitude less than 2000 feet AGL unless otherwise indicated, when in the vicinity of herds of wild animals or above wildlife refuges/bird sanctuaries depicted on affected aeronautical charts.

The landing or take-off of aircraft in areas designated as bird sanctuaries may require a permit. Contact information for bird sanctuaries can be found at Environment and Climate Change Canada's Web site: www.ec.gc.ca/ap-pa/default.asp?lang=En&n=0843985D-1.

Contact information for provincial and territorial game officers, and information concerning the preservation of wildlife within the various provinces and territories in Canada, can be found in the *AIP Canada (ICAO)* on the NAV CANADA Web site at: www.navcanada.ca/EN/products-and-services/Pages/AIP-part-2-current.aspx.

Information pertaining to the *Migratory Bird Regulations* may be obtained at http://laws-lois.justice.gc.ca/eng/regulations/C.R.C.,_c._1035/index.html or by contacting:

CA 1 GENERAL

Assistant Deputy Minister
Canadian Wildlife Service
Environment and Climate Change Canada

Address: Ottawa
ON
K1A 0H3
Tel: 1-800-668-6767
E-Mail: ec.enviroinfo.ec@canada.ca

1.13.3 National, Provincial and Municipal Parks, Reserves and Refuges

To preserve the natural environment of parks, reserves and refuges and to minimize the disturbance to the natural habitat, overflights should not be conducted below 2000 feet AGL. To assist pilots in observing this, boundaries are depicted on the affected charts.

The landing or take-off of aircraft in the national parks and national park reserves may take place at prescribed locations. Contact information for each location can be found on the Parks Canada website here: <http://www.pc.gc.ca>.

Additional details can be found in the *National Parks Aircraft Access Regulations* available here: <http://laws-lois.justice.gc.ca/eng/regulations/SOR-97-150/page-1.html>.

1.14 BIRD MIGRATION AND AREAS WITH SENSITIVE FAUNA

1.14.1 Wildlife Hazards

Trends indicate that there is a growing risk of collisions between wildlife and aircraft. This risk is due largely to corresponding increases in the populations of some hazardous species—such as deer, geese and gulls—and the numbers of aircraft operations across Canada.

All aviation stakeholders have a role to play in reducing the risks of wildlife strikes. Pilots can take three simple steps to help improve safety:

- a. Increase awareness of wildlife and the hazards they pose to aviation.
- b. Learn what risk-reduction and communication measures are in place at frequented airports.
- c. Become familiar with the bird/wildlife strike report form, and be sure to file a report in the event of any wildlife encounter.

This section provides information to help pilots gain a better appreciation of:

- measures airports must take to identify and control wildlife hazards, and to communicate with pilots about these hazards;
- bird/wildlife-strike reporting procedures; and
- migratory bird activity.

**CA 1
GENERAL****1.14.2 Airport Wildlife Management**

In force since May 16, 2006, a new CAR recognizes that lands on and around airports often provide food and shelter for wildlife species that can be hazardous to air travel. Division III of CAR 302—*Airport Wildlife Planning and Management*, requires most Canadian certified airports to minimize risks, primarily by identifying and countering potentially hazardous species. Airports that are subject to the regulation must develop, implement and maintain plans for the management of these species.

The process of identifying wildlife hazards and measuring the risks they pose is called risk analysis. Under CAR 302, an airport operator must conduct a risk analysis as one of the first steps in creating an airport wildlife management plan. Pilots should be aware that these analyses must include consultations with representative samples of airport users, such as flight schools, airlines and pilots.

1.14.3 Communication of Wildlife Hazards

Provisions of CAR 302 also require airport operators to put in place effective communication and alerting procedures to quickly notify pilots of wildlife hazards.

Pilots should monitor ATIS and air-ground communications for information concerning wildlife hazards, particularly during spring and autumn migration periods when bird activity is at its peak. In unusual circumstances, a NOTAM may be used to identify these hazards.

Pilots who encounter wildlife on an airport are asked to immediately notify ATS, and take appropriate steps to minimize the risk associated with their flight.

Pilots who frequent Canadian certified airports are encouraged to ask about measures in place to ensure effective communication and to counter wildlife hazards.

1.14.4 Bird/Wildlife-Strike Reporting Procedures

To comply with CAR 302, airport wildlife management plans must be based on current wildlife-strike data, which is compiled by, and made available through, Transport Canada. Airports must report all bird/wildlife strikes to Transport Canada and keep records of these events; however, bird/wildlife strike reports can be filed by anyone, including airline personnel, ground crews and pilots.

Strike reporting is one of the most valuable contributions members of the aviation community can make in an effort to reduce wildlife risks. The data is vital to national and international airport wildlife management efforts, and one of the most important tools in tracking wildlife trends and determining hazards at locations across Canada.

Pilots are asked to report any knowledge of bird/wildlife strikes, no matter how inconsequential the event may seem. Even information about a near miss can help authorities learn more about the presence of potentially-hazardous species, and the nuances of encounters between aircraft and wildlife.

In cases of bird strikes, reports should include the species whenever possible. Species identification provides airport operators with important data that enables them to effectively focus risk mitigation efforts. If the species is unknown, but bird remains are available from the incident, pilots

CA 1 GENERAL

may consult with airport wildlife management personnel for help identifying the species. Airport personnel may also decide to submit the remains for DNA analysis if they are unable to identify them.

CAR 302 requires an airport operator to amend its wildlife management plan, and submit it to Transport Canada for review within 30 days of the amendment, if a turbine-powered aircraft:

- suffers damage as a result of a collision with wildlife other than a bird;
- collides with more than one bird; or
- ingests a bird through an engine.

This process of review and amendment helps ensure wildlife management plans are as current as possible, addressing continual fluctuations in the wildlife hazards at airports. The review-and-amendment process is also set in motion when a variation in the presence of wildlife hazards is observed in an airport's flight pattern or movement area. Pilots can help mitigate risk by reporting to Transport Canada any significant changes in the numbers or behavior of hazardous wildlife at airports that are visited regularly.

1.15 POTENTIAL FLIGHT HAZARDS FOR AIRCRAFT

1.15.1 Avoid Flight in the Vicinity of Exhaust Plumes

CA 1 GENERAL

Exhaust plumes are defined as visible or invisible emissions from power plants, industrial production facilities or other industrial systems that release large amounts of vertically directed unstable gases. High temperature exhaust plumes may cause significant air disturbances, such as turbulence and vertical shear. Other identified potential hazards include, but are not necessarily limited to, reduced visibility, oxygen depletion, engine particulate contamination, exposure to gaseous oxides, and/or icing.

When able, pilots should fly upwind of possible exhaust plumes. Encountering a plume may result in airframe damage, aircraft upset, and/or engine damage/failure. These hazards are most critical during low altitude flight in calm and cold air, especially in and around approach and departure corridors or airport traffic areas.

When a plume is visible via smoke or a condensation cloud, remain clear and realize that a plume may have both visible and invisible characteristics. Exhaust stacks without visible plumes may still be in full operation, and airspace in the vicinity should be treated with caution. As with mountain wave turbulence or clear air turbulence, an invisible plume may be encountered unexpectedly.

Whether plumes are visible or invisible, the total extent of their turbulent affect is difficult to ascertain. Some studies predict that significant turbulent effects of a thermal plume can extend to heights of over 1000 ft above the height of the top of the stack or cooling tower. Any effects will be more pronounced in calm stable air where the plume is very hot and the surrounding area is still and cold. Fortunately, studies also predict that crosswinds will help dissipate the effects. However, the size of the tower or stack is not a good indicator of the plume's predicted effect. The effects are primarily related to the heat or size of the plume effluent, the ambient air temperature, and the wind speed affecting the plume. Smaller aircraft can expect to feel an effect at a higher altitude than heavier aircraft.

Pilots are encouraged to reference the CFS where notations caution pilots of the location of structure(s) emitting exhaust plumes, such as cooling towers, power plant stacks, exhaust fans and other similar structures.

Pilots encountering hazardous plume conditions should report time, location and intensity (light, moderate, severe or extreme) to the facility with which they are maintaining radio contact.

1.16 CANADIAN RUNWAY FRICTION INDEX (CRFI)

1.16.1 General

The following paragraphs discuss the slippery runway problem, and suggest methods of applying runway coefficient of friction information to Aircraft Flight Manual (AFM) data.

1.16.2 Reduced Runway Coefficients of Friction and Aircraft Performance

The accelerate-stop distance, landing distance and crosswind limitations (if applicable) contained in the aircraft flight manual (AFM) are demonstrated in accordance with specified performance criteria on runways that are bare, dry, and which have high surface friction characteristics. Unless some factor has been applied, these distances are valid only under similar runway conditions. Whenever a contaminant such as water, snow or ice is introduced to the runway surface, the effective coefficient of friction between the aircraft tire and runway is substantially reduced. The stop portion of the accelerate-stop distance will increase, the landing distance will increase and a

CA 1 GENERAL

crosswind may present directional control difficulties. The problem has been to identify, with some accuracy, the effect that the contaminant has had on reducing the runway coefficient of friction and to provide meaningful information to the pilot; e.g., how much more runway is needed to stop and what maximum crosswind can be accepted.

1.16.3 Description of CRFI and Method of Measurement

The decelerometer is an instrument that is mounted in a test vehicle and measures the decelerating forces acting on the vehicle when the brakes are applied. The instrument is graduated in increments from 0 to 1, the top number being equivalent to the theoretical maximum decelerating capability of the vehicle on a dry surface. These numbers are referred to as the CRFI. It is evident that small numbers represent low braking coefficients of friction while numbers on the order of 0.8 and above indicate the braking coefficients to be expected on bare and dry runways.

The brakes are applied on the test vehicle at 300m (1000 ft) intervals along the runway within a distance of 10m (30 ft) from each side of the runway centerline at that distance from the centerline where the majority of aircraft operations take place at each given site. The readings taken are averaged and reported as the CRFI number.

1.16.4 Description of Canadian Runway Friction Index (CRFI) Reporting Method

Where an airport receives airplane operations in an air transport service under Subpart 5 of Part VII of the CARs, CRFI is reported by runway thirds for runways greater than or equal to 1829m (6000 ft) in length.

CRFI may be reported by runway thirds for runways less than 1829m (6000 ft) in length where the airport is equipped to do so; however, CRFI will be reported by full runway lengths as a default.

The airport's winter maintenance plan should be consulted for the latest information on CRFI reporting methodology for a given runway.

1.16.5 Aircraft Movement Surface Condition Reports (AMSCR)

AMSCRs are issued to alert pilots of natural surface contaminants—such as snow, ice or slush—that could affect aircraft braking performance. The RSC section of the report provides information about runway condition in plain language, while the CRFI section describes braking action quantitatively using the numerical format described in paragraph 1.17.3.

Where runway information is reported in thirds, a runway condition code (RWYCC) is reported for each third. RWYCCs are on a scale of 0 to 6, where 0 represents the most slippery conditions and 6 represents dry runway performance.

AMSCRs are issued when contaminants are present on a movement area as follows:

- a. at the commencement of published AMSCR hours;
- b. a minimum of once every eight hours thereafter;
- c. when a significant change in a runway surface condition occurs;
- d. following every accident or incident in which winter conditions may have been a factor; and
- e. whenever the cleared width of the runway falls below full width.

**CA 1
GENERAL**

When available, a CRFI reading will be issued along with the RSC in order to provide an overall descriptive picture of the runway condition and to quantify braking action. Due to mechanical and operational limitations, the runway friction readings produced by decelerometers may be inaccurate under certain surface conditions. As a result, runway friction readings will be taken and a CRFI will be provided to ATS or to pilots only when any of the following conditions are present:

- a. ice;
- b. wet ice consisting of a thin film of water on ice;
- c. compacted snow;
- d. slush on ice;
- e. dry snow not exceeding 2.5 cm (1 in.) in depth;
- f. de-icing chemical solution or sand on ice; or
- g. frost.

An RSC report must be issued for each CRFI measurement provided.

The following changes relating to runway conditions are considered significant:

- a. any change in the RWYCC (if applicable);
- b. a CRFI change of 0.05 or more;
- c. any change in the contaminant type;
- d. any change of 20% or more in the reportable contaminant coverage;
- e. any change in contaminant depth of $\frac{1}{8}$ in. for standing water and slush, $\frac{1}{4}$ in. for wet snow, and $\frac{3}{4}$ in. for dry snow; and
- f. any other information that, according to assessment techniques, is considered to be significant, for example following the application or removal of sand or chemicals; following snow removal or sweeping; or following changes in conditions caused by rapid increases or decreases in temperature.

The depth of deposit is expressed in inches or feet or both. When the depth is above 2 in., whole values are used. When the depth is less than 2 in., fractions are used. The accepted fraction values are $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$ and $1 \frac{1}{2}$; however, caution has to be exercised as these values could be confused with CRFI measurements. When the depth of deposit is below $\frac{1}{8}$ in., the accepted depth is reported as $\frac{1}{8}$ in.

When clearing is not underway or expected to begin within the next 30 minutes, a notation such as "Clearing expected to start at (time in UTC)" will be added to the RSC report. When the meteorological conditions cause runway surface conditions to change frequently, the RSC NOTAM will include the agency and telephone number to contact for the current runway conditions.

The full range of RSC/CRFI information will be available as a voice advisory from the control tower at controlled airports and from the FSS at uncontrolled airports.

CA 1 GENERAL

Each new RSC NOTAM (AMSCR report) issued supersedes the previous report for that airport. An RSC NOTAM is valid for 8 hours or 24 hours, based on the most recent observation of either the RSC or CRFI, after which time it is removed from the database. An RSC NOTAM may also be cancelled if the reporting requirements are no longer met or the RSC NOTAM was issued in error.

NOTE: The absence of an RSC NOTAM in no way indicates that runway conditions are acceptable for operations.

The CRFI portion of the report is titled ADDN NON-GRF/TALPA INFO: and is in the following format: title (CRFI), runway number, temperature (in degrees Celsius), runway CRFI reading by full runway length or by runway thirds, and the observation time of the report using the 10-digit date-time group format in UTC (YYMMDDHHMM).

An RSC NOTAM is issued based on reporting requirements rather than on dissemination criteria. Therefore, conditions such as “dry” or “wet” will be disseminated if reported.

Information on taxiways and aprons, although not mandatory, can be disseminated in an RSC NOTAM if deemed to have an impact on safe operations.

1.16.6 Wet Runways

Runway friction values are currently not provided during the summer and when it is raining. Consequently, some discussion of wet runways is in order to assist pilots in developing handling procedures when these conditions are encountered.

A packed snow or ice condition at a fixed temperature presents a relatively constant coefficient of friction with speed, but this is not the case for a liquid (water or slush) state. This is because water cannot be completely squeezed out from between the tire and the runway and as a result, there is only partial tire-to-runway contact. As the aircraft speed is increased, the time in contact is reduced further, thus braking friction coefficients on wet surfaces fall as the speed increases, i.e., the conditions in effect become relatively more slippery, but will again improve as the aircraft slows down. This situation is further complicated by the susceptibility of aircraft tires to hydroplane on wet runways.

Hydroplaning is a function of the water depth, tire pressure and speed. Moreover, the minimum speed at which a non-rotating tire will begin to hydroplane is lower than the speed at which a rotating tire will begin to hydroplane because a build up of water under the non-rotating tire increases the hydroplaning effect. Pilots should therefore be aware of this since it will result in a substantial difference between the take-off and landing roll aircraft performance under the same runway conditions. The minimum speed, in knots, at which hydroplaning will commence can be calculated by multiplying the square root of the tire pressure (PSI) by 7.7 for a non-rotating tire, or by 9 for a rotating tire.

This equation gives an approximation of the minimum speed necessary to hydroplane on a smooth, wet surface with tires that are bald or have no tread. For example, the minimum hydroplaning speeds for an aircraft with tires inflated to 49 PSI are calculated as:

NON-ROTATING TIRE: $7.7 \times \sqrt{49} = 54 \text{ KT}$; or

ROTATING TIRE: $9 \times \sqrt{49} = 63 \text{ KT}$

CA 1 GENERAL

When hydroplaning occurs, the tires of the aircraft are completely separated from the actual runway surface by a thin water film and they will continue to hydroplane until a reduction in speed permits the tire to regain contact with the runway. This speed will be considerably below the speed at which hydroplaning commences. Under these conditions, the tire traction drops to almost negligible values and in some cases the wheel will stop rotating entirely. The tires will provide no braking capability and will not contribute to the directional control of the aircraft. The resultant increase in stopping distance is impossible to predict accurately, but it has been estimated to increase as much as 700%. Further, it is known that a 10 KT crosswind will drift an aircraft off the side of a 200 foot wide runway in approximately seven seconds under hydroplaning conditions.

Notwithstanding the fact that friction values cannot be given for a wet runway and that hydroplaning can cause pilots serious difficulties, it has been found that, under light or moderate rain conditions, well-drained runways seldom accumulate sufficient standing water for hydroplaning to occur.

1.16.7 CRFI Application to Aircraft Performance

The information contained in Tables 1 and 2 has been compiled and is considered to be the best data available at this time because it is based upon extensive field test performance data of aircraft braking on winter contaminated surfaces. The information should provide a useful guide to pilots in estimating aircraft performance under adverse runway conditions. The onus for the production of information, guidance or advice on the operation of aircraft on a wet and/or contaminated runway rests with the aircraft manufacturer. The information published in this AWM does not change, create any additional, authorize changes in, or permit deviations from regulatory requirements. These tables are intended to be used at the pilot's discretion.

Because of the many variables associated with computing accelerate-stop distances and balanced field lengths, it has not been possible to reduce the available data to the point where CRFI corrections can be provided which would be applicable to all types of operations. Consequently, only corrections for landing distances and crosswinds are included pending further study of the take-off problem.

It should be noted that in all cases the tables are based on corrections to aircraft flight manual (AFM) dry runway data and that the certification criteria does not allow consideration of the extra decelerating forces provided by reverse thrust or propeller reversing. On dry runways, thrust reversers provide only a small portion of the total decelerating forces when compared to wheel braking. However, as wheel braking becomes less effective, the portion of the stopping distance attributable to thrust reversing becomes greater. For this reason, if reversing is employed when a low CRFI is reported, a comparison of the actual stopping distance with that shown in Table 1 will make the estimates appear overly conservative. Nevertheless, there are circumstances such as crosswind conditions, engine out situations or reverser malfunction that may preclude their use.

Landing distances recommended in Table 1 are intended to be used for aircraft with no discing and/or reverse thrust capability, and are based on statistical variation measured during actual flight tests.

Notwithstanding the above comments on the use of discing and/or reverse thrust, Table 2 may be used for aircraft with discing and/or reverse thrust capability, and is based on the landing distance

CA 1 GENERAL

ces recommended in Table 1 with additional calculations that give credit for discing and/or reverse thrust. In calculating the distances in Table 2, the air distance from the screen height of 50 feet to touchdown and the delay distance from touchdown to the application of full braking remain unchanged from Table 1. The effects of discing and/or reverse thrust were used only to reduce the stopping distance from the application of full braking to a complete stop.

The recommended landing distances stated in Table 2 take into account the reduction in landing distances obtained with the use of discing and/or reverse thrust capability for a turboprop-powered airplane and with the use of reverse thrust for a turbojet-powered airplane. Representative low values of discing and/or reverse thrust effect have been assumed and, therefore the data may be conservative for properly executed landings by some aircraft with highly effective discing and/or thrust reversing systems.

The crosswind limits for CRFI shown in Table 3 contain a slightly different display range of runway friction index values from those listed in Tables 1 and 2. However, the CRFI values used for Table 3 are exactly the same as those used for Tables 1 and 2 and are appropriate for the index value increments indicated.

CA 1 GENERAL

Application of the CRFI

- a. The recommended landing distances in Table 1 are based on a 95% level of confidence. A 95% level of confidence means that in more than 19 landings out of 20, the stated distance in Table 1 will be conservative for properly executed landings with all systems serviceable on runway surfaces with the reported CRFI.
- b. Table 1 will also be conservative for turbojet and turboprop powered airplanes with reverse thrust, and additionally, in the case of turboprop powered airplanes, with the effect obtained from discing.
- c. The recommended landing distance in the CRFI Table 1 are based on standard pilot techniques for minimum distance landings from 50 feet including a stabilized approach at V_{ref} using a glideslope of 3° to 50 ft or lower, a firm touchdown, minimum delay to nose lowering, minimum delay time to deployment of ground lift dump devices and application of brakes, and sustained maximum antiskid braking until stopped.
- d. Landing field length is the landing distance divided by 0.6 (turbojets) or 0.7 (turboprops). If the Aircraft Flight Manual (AFM) expresses landing performance in terms of landing distance, enter the table from the left-hand column. However, if the AFM expresses landing performance in terms of landing field length, enter the table from one of the right-hand columns, after first verifying which factor has been used in the AFM.

Application of the CRFI

- The recommended landing distances in Table 2 are based on a 95% level of confidence. A 95% level of confidence means that in more than 19 landings out of 20, the stated distance in Table 2 will be conservative for properly executed landings with all systems serviceable on runway surfaces with the reported CRFI.
- The recommended landing distances in Table 2 take into account the reduction in landing distances obtained with the use of discing and/or reverse thrust capability for a turboprop-powered airplane and with the use of reverse thrust for a turbojet-powered airplane. Table 2 is based on the landing distances recommended in Table 1 with additional calculations that give credit for discing and/or reverse thrust. Representative low values of discing and/or reverse thrust effect have been assumed, hence the data will be conservative for properly executed landings by some airplanes with highly effective discing and/or thrust reversing systems.
- The recommended landing distances in CRFI Table 2 are based on standard pilot techniques for the minimum distance landings from 50 ft., including a stabilized approach at V_{ref} using a glideslope of three degrees to 50 ft or lower, a firm touchdown, minimum delay to nose lowering, minimum delay time to deployment of ground lift dump devices and application of brakes and discing and/or reverse thrust, and sustained maximum antiskid braking until stopped. In Table 2, the air distance from the screen height of 50 ft to touchdown and the delay distance from touchdown to the application of full braking remain unchanged from Table 1. The effects of discing/reverse thrust were used only to reduce the stopping distance from the application of full braking to a complete stop.

**CA 1

- d. Landing field length is the landing distance divided by 0.6 (turbojets) or 0.7 (turboprops). If the AFM expresses landing performance in terms of landing distance, enter the table from the left-hand column. However, if the AFM expresses landing performance in terms of landing field length, enter the table from one of the right-hand columns, after first verifying which factor has been used in the AFM.

CA 1
GENERAL

Table 3 Crosswind Limits for CRFI

This chart provides information for calculating headwind and crosswind components and the vertical lines indicate the recommended maximum crosswind component for reported CRFI.

EXAMPLE: CYOW CRFI 07/25 -4C .30 1201191200

**CA 1
GENERAL**

Tower Wind 110 degrees 20 KT

The wind is 40 degrees off the runway heading and produces a headwind component of 15 KT and a crosswind component of 13 KT. The recommended minimum CRFI for a 13 KT crosswind component is .35. A take-off or landing with a CRFI of .3 could result in uncontrollable drifting and yawing.

The CRFI depends on the surface type, as shown in Table 4a. It should be noted that:

- a. the CRFI values given in Table 4a are applicable to all temperatures. Extensive measurements have shown that there is no correlation between the CRFI and the surface temperature. The case where the surface temperature is just at the melting point (i.e. about 0°C) may be an exception, as a water film may form from surface melting, which could induce slippery conditions with CRFIs less than those in Table 4a.
- b. the CRFI may span a range of values for various reasons, such as variations in texture among surfaces within a given surface class. The expected maximum and minimum CRFIs for various surfaces are listed in Table 4b. Note that these values are based on a combination of analyses of extensive measurements and sound engineering judgment.
- c. the largest range in CRFI is to be expected for a thin layer (3mm or less in thickness) of dry snow on pavement (Table 4a). This variation may occur due to:
 - (i) non-uniform snow coverage; and/or
 - (ii) the tires breaking through the thin layer

In either case, the surface presented to the aircraft may range from snow to pavement.

CA 1
GENERAL

Table 4a Expected Range of CRFIs by Surface Type

Table 4b Minimum and Maximum CRFIs for Various Surfaces

SURFACE	LOWER CRFI LIMIT	UPPER CRFI LIMIT
Bare Ice	No Limit	0.3
Bare Packed Snow	0.1	0.4
Sanded Ice	0.1	0.4
Sanded Packed Snow	0.1	0.5
Dry Snow on Ice (depth 3mm or less)	No Limit	0.4
Dry Snow on Ice (depth 3 to 25mm)	No Limit	0.4
Dry Snow on Packed Snow (depth 3mm or less)	0.1	0.4
Dry Snow on Packed Snow (depth 3 to 25mm)	0.1	0.4
Dry Snow on Pavement (depth 3mm or less)	0.1	Dry Pavement
Dry Snow on Pavement (depth 3mm to 25mm)	0.1	Dry Pavement

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

SECTION 2**2.1 GENERAL**

Canadian airspace is divided into a number of categories which in turn are subdivided into a number of areas and zones. The various rules are simplified by the classification of all Canadian airspace. This section describes these in detail as well as the regulations and procedures specific to each. The official designation of all airspace is published in the DAH. Canadian airspace is managed by NAV CANADA in accordance with the terms established for the transfer of the air navigation system (ANS) from government operation to NAV CANADA and with the rights granted to the corporation pursuant to the *Civil Air Navigation Services Commercialization Act*.

2.2 CANADIAN DOMESTIC AIRSPACE

Canadian Domestic Airspace (CDA) includes all airspace over the Canadian land mass, the Canadian Arctic, Canadian Archipelago, and those areas of the high seas within the airspace boundaries. These boundaries are depicted on the Enroute Charts.

2.2.1 Northern Domestic Airspace

Canadian Domestic Airspace is geographically divided into the Southern Domestic Airspace and the Northern Domestic Airspace as indicated in Figure 2.1. In the Southern Domestic Airspace, magnetic track is used to determine cruising altitude for direction of flight.

The Magnetic North Pole is located near the center of the Northern Domestic Airspace, therefore magnetic compass indications may be erratic. Thus, in this airspace, runway heading is given in true and true track is used to determine cruising altitude for direction of flight in lieu of magnetic track.

CA 2
AIRSPACE REQUIREMENTS AND PROCEDURES

Figure 2.1 — Boundaries of Canadian Domestic Airspace, Northern Domestic Airspace and Southern Domestic Airspace

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

2.3 HIGH AND LOW LEVEL AIRSPACE

The Canadian Domestic Airspace is further divided vertically into Low Level Airspace, which consists of all of the airspace below 18,000 feet ASL; and High Level Airspace which consists of all airspace from 18,000 feet ASL and above.

2.3.1 Cruising Altitudes and Flight Levels Appropriate to Aircraft Track

2.3.1.1 General Provisions

- a. The appropriate altitude or flight level for aircraft in level cruising flight is determined in accordance with:
 1. the magnetic track, in SDA; and
 2. the true track, in NDA.
- b. When an aircraft is operated in level cruising flight:
 1. at more than 3000 ft AGL, in accordance with VFR;
 2. in accordance with IFR; or
 3. during a CVFR flight;

the pilot-in-command of an aircraft shall ensure that the aircraft is operated at an altitude or flight level appropriate to the track, unless he/she is assigned an altitude or flight level by an ATC unit or by written authority from the Minister.

- c. RVSM cruising flight levels appropriate to aircraft track are applicable in designated RVSM airspace.
- d. The pilot-in-command of an aircraft operating within controlled airspace between 18,000 ft ASL and FL600, inclusive, shall ensure that the aircraft is operated in accordance with IFR unless otherwise authorized in writing by the Minister. (CAR 602.34)

NOTE: As per the table in CAR 602.34(2), a vertical separation of 2000 ft is required from FL290 to FL410 inclusive.

ALTITUDES OR FLIGHT LEVELS	AIRCRAFT TRACK	
	000° – 179°	180° – 359°
Above flight level 290: fly 4000 ft intervals.	Beginning at flight level 290 (FL290, 330, 370, 410, 450)	Beginning at flight level 310 (FL310, 350, 390, 430, 470)
RVSM	FL290, 310, 330, 350, 370, 390, 410	FL300, 320, 340, 360, 380, 400
At or above 18,000 ASL but below FL290: fly 2000 ft intervals.	Odd flight levels (FL190, 210, 230, etc.)	Even flight levels (FL180, 200, 220, etc.)
Below 18,000 ASL: (fly corresponding flight levels in stand-	IFR and CVFR	IFR and CVFR

CA 2 AIRSPACE REQUIREMENTS AND PROCEDURES

ALTITUDES OR FLIGHT LEVELS	AIRCRAFT TRACK	
	000° – 179°	180° – 359°
	and pressure region) fly 2000 ft intervals.	Odd thousands ASL (1000, 3000, 5000, etc.)
	VFR	Even thousands ASL (2000, 4000, 6000, etc.)
	Odd thousands plus 500 ft ASL (3500, 5500, 7500, etc.)	Even thousands plus 500 ft ASL (4500, 6500, 8500, etc.)

Figure 2.2 — Flight Information Regions

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

2.4 FLIGHT INFORMATION REGIONS

A Flight Information Region (FIR) is an airspace of defined dimensions extending upwards from the surface of the earth, within which flight information service and alerting services are provided. The Canadian Domestic Airspace is divided into the Vancouver, Edmonton, Winnipeg, Toronto, Montreal, Moncton and Gander Domestic Flight Information Regions. Gander Oceanic is an additional FIR allocated to Canada by ICAO for the provision of flight information and alerting services over the high seas.

Canadian Flight Information Regions are depicted on the Jeppesen Enroute Charts, and also illustrated in Figure 2.2.

Agreements have been effected between Canada and the United States to permit reciprocal air traffic control services outside of the designated national FIR boundaries. An example is V300 and J500 between SSM and YQT. The control of aircraft in U.S. airspace delegated to a Canadian ATC unit is effected by applying the Canadian rules, procedures and separation minima with the following exceptions:

- a. aircraft will not be cleared to maintain “1000 feet on top”;
- b. ATC vertical separation will not be discontinued on the basis of visual reports from the aircraft; and
- c. Canadian protected airspace criteria for track separation will not be used.

2.5 CONTROLLED AIRSPACE

Controlled airspace is the airspace within which air traffic control service is provided and within which some or all aircraft may be subject to air traffic control. Types of controlled airspace are:

- a. In the High Level Airspace:
 - The Southern, Northern and Arctic Control Areas.

NOTE: Encompassed within the above are high level airways, the upper portions of some military terminal control areas and terminal control areas.

- b. In the Low Level Airspace:
 - low level airways,
 - terminal control areas,
 - control area extensions,
 - control zones,
 - transition areas, and
 - military terminal control areas.

2.5.1 Use of Controlled Airspace by VFR Flights

Due to the speeds of modern aircraft, the difficulty in visually observing other aircraft at high altitudes, and the density of air traffic at certain locations and altitudes, the “see and be seen” principle of VFR separation cannot always provide positive separation. Accordingly, in certain airspace

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

and at certain altitudes VFR flight is either prohibited or subject to specific restrictions prior to entry and during flight.

2.5.2 Aircraft Speed Limit Order

According to CAR 602.32, no person shall operate an aircraft in Canada:

- a. below 10,000 ft ASL at more than 250 KIAS; or
- b. below 3000 ft AGL within 10 NM of a controlled airport at more than 200 KIAS, unless authorized to do so in an air traffic control clearance.

Exceptions

- a. A person may operate an aircraft at an indicated airspeed greater than the airspeeds referred to in (a) and (b) above where the aircraft is being operated in accordance with a special flight operations certificate — special aviation event issued under CAR 603.
- b. If the minimum safe speed, given the aircraft configuration, is greater than the speed referred to in (a) or (b) above, the aircraft shall be operated at the minimum safe speed.

Notifying ATC

On departure, when intending to operate at speeds exceeding 250 KIAS below 10,000 ft ASL, pilots must, on initial contact, notify the departure controller of the reason for this action.

ATC requires this information for the following reasons:

- for operational considerations regarding other traffic, particularly in potential overtake situations; and
- so that ATC will know that the request or notification of intent to operate above the speed limit is for “*minimum safe speed*” requirements and will therefore not file an Aviation Occurrence Report.

The phraseology of “*minimum safe speed XXX kt*” is encouraged and ATC will acknowledge.

EXAMPLE: *Montreal Centre, ACA123, minimum safe speed 270 kt.*

As ATC is not authorized to approve a speed greater than 250 KIAS below 10,000 ft ASL, the phraseology “request high-speed climb” should not be used.

2.6 HIGH LEVEL CONTROLLED AIRSPACE

Controlled airspace within the High Level Airspace is divided into three separate areas. They are the Southern Control Area (SCA), the Northern Control Area (NCA), and the Arctic Control Area (ACA). Their lateral dimensions are illustrated in Figure 2.3. Figure 2.4 illustrates their vertical dimensions which are: SCA, 18,000 ft ASL and above; NCA, FL230 and above; ACA, FL270 and above.

Pilots are reminded that both the NCA and the ACA are within the Northern Domestic Airspace, therefore compass indications may be erratic and true tracks are used in determining the flight level at which to fly. In addition, the airspace from FL330 to FL410 within the lateral dimensions of the NCA, the ACA and the northern part of the SCA has been designated CMNPS airspace.

CA 2
AIRSPACE REQUIREMENTS AND PROCEDURES

Figure 2.3 — Southern, Northern and Arctic Control Areas

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

Figure 2.4 — Vertical Dimensions of Southern, Northern and Arctic Control Areas

2.7 LOW LEVEL CONTROLLED AIRSPACE

2.7.1 Low Level Airways

Controlled Low Level Airspace extends upwards from 2200 ft AGL up to, but not including, 18,000 ft ASL, within the following specified boundaries:

a. *VHF/UHF Airways*

The basic VHF/UHF airway width is 4 NM on each side of the center line prescribed for such an airway. Where applicable, the airway width shall be increased between the points where lines, diverging 4.5° on each side of the center line from the designated facility, intersect the basic width boundary and where they meet, similar lines projected from the adjacent facility.

Figure 2.5(a) — VHF/UHF Airway Dimensions

Where a Victor airway is established based on a VOR/VORTAC and NDB, the boundaries of that airway will be those of an LF/MF airway [see Figure 2.5(b)].

CA 2 AIRSPACE REQUIREMENTS AND PROCEDURES

Figure 2.5(b) — VHF/UHF Airway Based on VOR and NDB

Figure 2.6 — LF/MF Airway Dimensions

b. LF/MF Airways

The basic LF/MF airway width is 4.34 NM on each side of the center line prescribed for such an airway. Where applicable, the airway width shall be increased between the points where lines, diverging 5° on each side of the center line from the designated facility, intersect the basic width boundary; and where they meet, similar lines projected from the adjacent facility.

- c. **T-Routes:** Low-level controlled fixed RNAV routes have dimensions of 4 NM of primary obstacle protection area, plus 2 NM of secondary obstacle protection area on each side of the centerline. The airspace associated with RNAV T-routes is 10 NM on each side of the centerline. RNAV T-route airspace and protection areas do not splay.

Figure 2.7(a) — Fixed RNAV Route

CA 2 AIRSPACE REQUIREMENTS AND PROCEDURES

Figure 2.7(b) — Fixed RNAV Route Cross Section

2.7.2 Control Area Extensions

Control area extensions are designated around airports where the controlled airspace provided is insufficient to permit the required separation between IFR arrivals and departures and to contain IFR aircraft within controlled airspace. A control area extension provides:

- additional controlled airspace around busy airports for IFR control. The controlled airspace contained within the associated control zone and airway(s) width is not always sufficient to permit the maneuvering required to separate IFR arrivals and departures; or
- connecting controlled airspace; e.g., a control area extension is used to connect a control zone with the enroute structure.

Control area extensions are based at 2200 ft AGL unless otherwise specified and extend up to, but not including, 18,000 ft ASL. Some control area extensions, such as those which extend to the oceanic controlled airspace, may be based at other altitudes such as 2000 ft, 5500 ft or 6000 ft ASL. The outer portions of some other control area extensions may be based at higher levels.

2.7.3 Control Zones

Control zones are designated around certain airports to keep IFR aircraft within controlled airspace during approaches and to facilitate the control of VFR and IFR traffic.

Control zones having a civil control tower within a terminal control area normally have a 7 NM radius. Others have a 5 NM radius, with the exception of a few which have a 3 NM radius. Control zones are capped at 3000 ft AAE unless otherwise specified. Military control zones usually have a 10 NM radius and are capped at 6000 ft AAE. All control zones are depicted on the VFR aeronautical charts and the Enroute Low Altitude Charts. Control zones will be classified B, C, D or E depending on the classification of the surrounding airspace.

The VFR weather minima for control zones are outlined in Figure 2.8. When weather conditions are below VFR minima, a pilot operating VFR may request Special VFR (SVFR) authorization in order to enter the control zone. This authorization is normally obtained through the local tower or FSS, and must be obtained before SVFR is attempted within a control zone. ATC will issue an

CA 2
AIRSPACE REQUIREMENTS AND PROCEDURES

SVFR authorization, traffic and weather conditions permitting, only upon a request for SVFR from a pilot. SVFR will not be initiated by ATS. Once having received a SVFR authorization, the pilot continues to remain responsible for avoiding other aircraft and weather conditions beyond the pilot's own flight capabilities and the capabilities of the aircraft.

Figure 2.8 — VFR Weather Minima*

AIRSPACE		FLIGHT VISIBILITY	DISTANCE FROM CLOUD	DISTANCE AGL
Control Zones		not less than 3 miles**	horizontally: 1 mile vertically: 500 feet	vertically: 500 feet
Other Controlled Airspace		not less than 3 miles	horizontally: 1 mile vertically: 500 feet	
Uncontrol- led Airspace	1000 feet AGL or above	not less than 1 mile (day) 3 miles (night)	horizontally: 2000 feet vertically: 500 feet	
	below 1000 feet AGL – all aircraft except helicopters	not less than 2 miles (day) 3 miles (night) (NOTE 1)	clear of cloud	
	below 1000 feet AGL – helicopter	not less than 1 mile (day) 3 miles (night) (NOTE 2)	clear of cloud	

* See CAR 602, Division VI — *Visual Flight Rules*

** Ground visibility when reported

NOTE 1: Notwithstanding CAR 602.115, an aircraft other than a helicopter may be operated in visibilities less than 2 miles during the day, when authorized to do so in an air operator certificate or in a private operator certificate.

NOTE 2: Notwithstanding CAR 602.115, a helicopter may be operated in visibilities less than 1 mile during the day, when authorized to do so in an air operator certificate or in a flight training unit operator certificate – helicopter.

Special VFR weather minimum and requirements applicable within control zones are found in CAR 602.117, and are summarized as follows:

Where authorization is obtained from the appropriate ATC unit, a pilot-in-command may operate an aircraft within a control zone in IFR weather conditions without compliance with the IFR, where flight visibility and, when reported, ground visibility are not less than:

- a. One mile for aircraft other than helicopters; and

CA 2
AIRSPACE REQUIREMENTS AND PROCEDURES

- b. 1/2 mile for helicopters.

NOTE 1: All aircraft, including helicopters, must be equipped with a radio capable of communicating with the ATC unit and must comply with all conditions issued by the ATC unit as part of the SVFR authorization.

NOTE 2: Aircraft must operate clear of cloud and within sight of the ground at all times.

NOTE 3: Helicopters should operate at such reduced airspeeds so as to give the pilot-in-command adequate opportunity to see other air traffic or obstructions in time to avoid a collision.

NOTE 4: When the aircraft is not a helicopter and is being operated at night, ATC will only authorize special VFR where the authorization is for the purpose of allowing the aircraft to land at the destination airport.

Figure 2.9 — Special VFR Weather Minima

	Flight Visibility (Ground when reported)	Distance from Cloud
Aircraft other than Helicopter	1 mile	Clear of cloud
Helicopter	1/2 mile	

2.7.4 VFR Over-the-Top

A person may operate an aircraft VFR Over-the Top (VFR OTT), provided certain conditions are met. Those conditions include weather minima, aircraft equipment and pilot qualifications. Pilots should indicate that the flight is VFR OTT during communications with ATS units. Deviations from the intended route of flight may be necessary when transiting CZs or TCAs. Pilots should take into consideration the additional fuel requirements this may cause.

CAR 602.116 specifies the weather minima for VFR OTT. A summary of the minima follows:

- a. VFR OTT is allowed during the day only, and during the cruise portion of the flight only.
- b. The aircraft must be operated at a vertical distance from cloud of at least 1000 feet.
- c. Where the aircraft is operated between two cloud layers, those layers must be at least 5000 feet apart.
- d. The flight visibility at the cruising altitude of the aircraft must be at least 5 miles.
- e. The weather at the destination airport must have a sky condition of scattered cloud or clear, and a ground visibility of 5 miles or more, with no forecast of precipitation, fog, thunderstorms, or blowing snow, and these conditions must be forecast to exist
 - 1. in the case of an aerodrome forecast (TAF), for the period from 1 hour before to 2 hours after the ETA; and
 - 2. in the case of an area forecast (GFA) because a TAF is not available, for the period from 1 hour before to 3 hours after the ETA.

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

CARs 605.14 and 605.15 outline the aircraft equipment requirements for VFR OTT. The equipment requirements, in part, are the same as for VFR flight, with extra requirements for VFR OTT.

Pilot qualifications for VFR OTT flight are specified in CARs, Part IV — *Personnel Licensing and Training*.

2.7.5 Transition Areas

Transition areas are established when it is considered advantageous or necessary to provide additional controlled airspace for the containment of IFR operations.

Transition areas are of defined dimensions, based at 700 ft AGL unless otherwise specified, and extend upwards to the base of overlying controlled airspace. The area provided around an airport will normally be 15 NM radius of the airport coordinates, but shall be of sufficient size to contain all of the airport published instrument approach procedures. Even if described with an ASL floor, the base of a transition area shall not extend lower than 700 ft AGL.

2.7.6 Terminal Control Areas

Terminal control areas are established at high volume traffic airports to provide an IFR control service to arriving, departing and enroute aircraft. Aircraft operating in the TCA are subject to certain operating rules and equipment requirements. The TCA operating rules are established by the classification of the airspace within the TCA. These rules will be based on the level of ATC service that is appropriate for the number and type of aircraft using the airspace as well as the nature of the operations being conducted.

A TCA is similar to a control area extension except that:

- a TCA may extend up into the high level airspace;
- IFR traffic is normally controlled by a terminal control unit (TCU). The ACC will control a TCA during periods when a TCU is not in operation; and
- TCA airspace will normally be designed in a circular configuration centered on the geographic coordinates of the primary airport. The outer limit of the TCA should be a 45 NM radius from the airport geographic coordinates based at 9500 ft AGL, with an intermediate circle at 35 NM based at 2200 ft AGL and an inner circle at 12 NM radius based at 1200 ft AGL. Where an operational advantage may be gained, the area may be sectorized. For publication purposes the altitudes may be rounded to the nearest appropriate increment and published as heights ASL. The floor of a TCA shall not extend lower than 700 ft AGL.

A military terminal control area is the same as a TCA, except that special provisions prevail for military aircraft while operating within the MTCA. MTCAs may be designated at selected military airports where the control service will be provided by a military TCU, or by ATC, through agreement with DND.

2.8 AIRSPACE CLASSIFICATION

Canadian Domestic Airspace (CDA) is divided into seven classes, each identified by a single letter — A, B, C, D, E, F, or G. Flight within each class is governed by specific rules applicable to

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

that class, and the rules are contained in *Canadian Aviation Regulation* CAR 601, which can be found at <<https://lois-laws.justice.gc.ca/eng/regulations/SOR-96-433/FullText.html#s-601.01>>.

The air traffic services available and the rules for operating within a particular portion of airspace depend on the classification of that airspace and not on the name by which it is commonly known. Thus, the air traffic services available and the rules for flight within a high-level airway, a terminal control area (TCA), or a control zone (CZ) depend on the class of airspace within all or part of the defined area. Weather minima are specified for controlled or uncontrolled airspace, not for each class of airspace. For more information on Canada's airspace classification and structure, please see Figure 2.10. A printable copy of Figure 2.10 is available at <https://tc.canada.ca/sites/default/files/migrated/tc_6010_airspaceposter_e.pdf>.

CA 2 AIRSPACE REQUIREMENTS AND PROCEDURES

Figure 2.10 — Canada's Airspace (TP 6010)

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

2.8.1 Class A Airspace

Class A airspace is designated where an operational need exists to exclude VFR aircraft.

All operations must be conducted under Instrument Flight Rules and are subject to ATC clearances and instructions. ATC separation is provided to all aircraft.

All aircraft operating in Class A airspace must be equipped with a transponder and automatic pressure altitude reporting equipment.

Class A airspace will be designated from the base of all high level controlled airspace, or from 700 ft AGL, whichever is higher, up to and including FL600.

2.8.2 Class B Airspace

Class B airspace is designated where an operational need exists to provide ATC service to IFR and to control VFR flights.

Operations may be conducted under IFR or VFR. All aircraft are subject to ATC clearances and instructions. ATC separation is provided between all aircraft. VFR flights are conducted as controlled VFR flights.

All low level controlled airspace above 12,500 ft ASL, or at and above the MEA, whichever is higher, up to but not including 18,000 ft ASL will be Class B airspace.

Control zones and associated terminal control areas may also be classified as Class B airspace.

NOTE:

a. No person shall operate an aircraft in Class B controlled airspace in VFR flight unless:

1. the aircraft is equipped with:

(a) radio communication equipment capable of two-way communication with the appropriate ATS facility, and

(b) radio navigation equipment capable of utilizing navigation facilities to enable the aircraft to be operated in accordance with the flight plan; and

(c) a transponder and automatic pressure altitude reporting equipment.

2. a continuous listening watch is maintained by a flight crew member on a radio frequency assigned by ATC;

3. except as otherwise authorized by ATC, when the aircraft is over a reporting point, a position report is transmitted to the appropriate unit or, when so directed by ATC, to an FSS; and

4. the aircraft is operated in VMC at all times.

b. A person operating an aircraft on a VFR flight in Class B airspace shall operate the aircraft in VMC at all times. When it becomes evident that flight in VMC will not be possible at the altitude or along the route specified, the pilot shall:

1. request an ATC clearance which will enable the aircraft to be operated in VMC to the filed destination, or to another airport;

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

- 2. where the person is the holder of a valid instrument rating, request an IFR clearance for flight under the instrument flight rules; or*
- 3. where the Class B airspace is a control zone, request an authorization for special VFR flight.*
- c. A person operating an aircraft in Class B controlled airspace in VFR flight who is unable to comply with the requirements of the preceding paragraphs shall ensure that:*
 - 1. the aircraft is operated in VMC at all times;*
 - 2. the aircraft leaves Class B controlled airspace:*
 - (a) by the safest and shortest route, either exiting horizontally or descending, or*
 - (b) when that airspace is a control zone, by landing at the airport on which the control zone is based, and*
 - 3. an ATC unit is informed as soon as possible of the actions taken pursuant to paragraph b).*

2.8.3**Class C Airspace**

Class C airspace is a controlled airspace within which both IFR and VFR flights are permitted, but VFR flights require a clearance from ATC to enter. ATC separation is provided between all aircraft operating under IFR. Conflict resolution is provided, when necessary, to resolve possible conflicts between VFR and IFR aircraft. All aircraft will be provided with traffic information. Conflict resolution between VFR aircraft can be provided upon request, after VFR aircraft are provided with traffic information. Runway separation is provided between all aircraft.

Traffic information is issued to advise pilots of known or observed air traffic, which may be in proximity to their aircraft's position or intended route of flight warranting their attention. Conflict resolution is defined as the resolution of potential conflicts between IFR/VFR and VFR aircraft that are radar identified and in communication with ATC.

Airspace classified as Class C becomes Class E airspace when the appropriate ATC unit is not in operation.

Terminal control areas and associated control zones may be classified as Class C airspace.

A person operating an aircraft in VFR flight in Class C airspace shall ensure that:

- a. the aircraft is equipped with
 1. radio communication equipment capable of two-way communication with the appropriate ATC unit; and
 2. a transponder and automatic pressure altitude reporting equipment; and
- b. a continuous listening watch is maintained by a flight crew member on a radio frequency assigned by ATC.

A person wishing to operate an aircraft that is not equipped with functioning communication and transponder equipment for VFR flights in Class C airspace may, during daylight hours and in

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

VMC, enter Class C airspace provided that permission to enter and to operate within the airspace is obtained from ATC prior to the operation being conducted.

2.8.4 Class D Airspace

Class D airspace is a controlled airspace within which both IFR and VFR flights are permitted, but VFR flights must establish two-way communication with the appropriate ATC unit prior to entering the airspace. ATC separation is provided only between IFR aircraft. Aircraft will be provided with traffic information. Equipment and workload permitting, conflict resolution will be provided between VFR and IFR aircraft, and upon request between VFR aircraft. Runway separation is provided between all aircraft.

Airspace classified as Class D becomes Class E airspace when the appropriate ATC unit is not in operation.

A terminal control area and associated control zone could be classified as Class D airspace.

A person operating an aircraft in VFR flight in Class D airspace shall ensure that:

- a. the aircraft is equipped with
 1. radio communication equipment capable of two-way communication with the appropriate ATC unit; and
 2. where the Class D airspace is specified as Transponder Airspace, a transponder and automatic pressure altitude reporting equipment; and
- b. a continuous listening watch is maintained by a flight crew member on a radio frequency assigned by ATC.

A person operating an aircraft in VFR flight that is not equipped with the required radio communication equipment may, during daylight hours in VMC, enter Class D airspace provided that permission to enter is obtained from the appropriate ATC unit prior to operating within the airspace.

2.8.5 Class E Airspace

Class E airspace is designated where an operational need exists for controlled airspace but does not meet the requirements for Class A, B, C, or D.

Operations may be conducted under IFR or VFR. ATC separation is provided only between aircraft operating under IFR. VFR aircraft do not require permission to enter Class E airspace and, except for mandatory frequency areas (see ATC — AIRPORT OPERATIONS — Mandatory Frequency (MF)), are not required to establish communication with an ATC unit prior to entering. Workload and equipment permitting, traffic information may be provided, upon request, to VFR aircraft. When requesting traffic information from ATC, pilots should be aware that air traffic controllers providing services in Class E airspace are responsible for larger volumes of airspace than those providing services in Class C or D airspace. As a result, there is a higher potential that workload and equipment limitations could affect the provision of traffic information, including potentially discontinuing this service without notification. A person operating an aircraft in VFR flight in Class E airspace remains responsible for maintaining a vigilant watch for, and avoiding, other traffic.

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

Aircraft are required to be equipped with a transponder and automatic pressure altitude equipment to operate in Class E airspace that is specified as transponder airspace.

Low level airways, control area extensions, transition areas, or control zones established without an operating control tower may be classified as Class E airspace.

2.8.6 Class F Airspace

Class F airspace is airspace of defined dimensions within which activities must be confined because of their nature, and within which limitations may be imposed upon aircraft operations that are not a part of those activities.

Class F airspace may be restricted airspace, advisory airspace, military operations areas, or danger areas and can be controlled airspace, uncontrolled airspace, or a combination of both. An advisory area, for example, may have the floor in uncontrolled airspace and the ceiling in controlled airspace. The significance, in this instance, is that the weather minima would be different in the controlled and uncontrolled portions.

Unless otherwise specified, the rules for the appropriate airspace apply in areas of Class F airspace, no matter if they are active or inactive.

Class F airspace is designated in the DAH (TP 1820) and published on the appropriate aeronautical charts.

2.8.6.1 Charting of Class F Airspace

All designated Class F restricted and advisory airspace is published on HI or LO Charts, as applicable, and on VFR aeronautical charts.

Each restricted and advisory area within Canada has been assigned an identification code group which consists of the four following parts:

- | | | | |
|----------|--|---|---|
| Part (a) | the nationality letters CY; | | |
| Part (b) | the letter R for restricted area, the letter A for advisory area, or the letter D for danger area; and | | |
| Part (c) | a three digit number that identifies the area. This number indicates the Canadian region within which the area lies, as follows: | | |
| | 101 to 199 | — | British Columbia |
| | 201 to 299 | — | Alberta |
| | 301 to 399 | — | Saskatchewan |
| | 401 to 499 | — | Manitoba |
| | 501 to 599 | — | Ontario |
| | 601 to 699 | — | Quebec |
| | 701 to 799 | — | New Brunswick, Nova Scotia, Prince Edward Island, Newfoundland and Labrador |

CA 2
AIRSPACE REQUIREMENTS AND PROCEDURES

- | | | |
|------------|---|---|
| 801 to 899 | — | Yukon Territory |
| 901 to 999 | — | Northwest Territories and Nunavut (including the Arctic Is) |

Part (d) in the case of advisory areas, the letter A, F, H, M, P, S or T in parentheses after the three-digit number that indicates the type of activity within the area, as follows:

- A — acrobatic
- F — aircraft test
- H — hang gliding
- M — military operations
- P — parachuting
- S — soaring
- T — training

EXAMPLE: The identification code group CYA113(A) means the following:

- | | | |
|-----|---|---|
| CY | — | indicates Canada |
| A | — | indicates advisory |
| 113 | — | indicates the number of an area in British Columbia |
| (A) | — | indicates acrobatic activity takes place within the area. |

All altitudes will be inclusive unless otherwise indicated, (e.g., 5000 to 10,000 ft). To indicate when either the bottom or upper altitude is not included, the words below and above will be placed before the appropriate altitude, (e.g., above 5000 to 10,000 ft, or 5000 to below 10,000 ft).

ATC will maintain separation between IFR aircraft and active Class F airspace unless:

- a. the pilot states that permission has been obtained from the user agency to enter the airspace;
- b. the aircraft is operating on an altitude reservation approval (ALTRV APVL); or
- c. the aircraft has been cleared for a contact or visual approach.

2.8.6.2 *Danger Area (International Waters)*

A danger area is Class F airspace that may be established over international waters but within Canada's area of responsibility for providing ATS, as agreed to with ICAO. This is an airspace of defined dimensions within which activities dangerous to the flight of aircraft may exist at specified times. ATC clearances will not be issued for non-participating flights to enter a danger area. Aircraft should avoid flight in danger areas unless participating in the activity taking place therein.

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

2.8.6.3 *Advisory Airspace*

Airspace may be classified as Class F advisory airspace if it is airspace within which activity occurs that, for flight safety proposes, non-participating pilots should be aware of, such as training, parachuting, hang gliding, and military operations.

Although not specifically restricted from operating therein, all aircraft are encouraged to avoid flight in advisory airspace unless participating in the activity taking place. If necessary, pilots of non-participating flights may enter advisory areas at their own discretion; however, extra vigilance is recommended. Pilots of participating aircraft, as well as pilots flying through the area, are equally responsible for collision avoidance. ATC will normally ensure that IFR aircraft in controlled airspace remain clear of Class F advisory airspace. IFR aircraft shall be provided 500 ft vertical separation from an active Class F advisory airspace, unless wake turbulence minima are applicable, in which case 1000 ft vertical separation shall be applied.

Pilots intending to fly in Class F advisory airspace are encouraged to monitor an appropriate frequency, to broadcast their intentions when entering and leaving the area, and to communicate, as necessary, with other users, to ensure flight safety in the airspace. In a Class F advisory uncontrolled airspace area, 126.7 MHz would be an appropriate frequency.

NOTE: Military operations in a Class F airspace may be UHF only.

2.8.6.4 *Restricted Airspace*

A restricted area is an airspace of defined dimensions above the land areas of territorial waters within which the flight of aircraft is restricted in accordance with certain specified conditions. Restricted airspace is designated for safety purposes when the level or type of aerial activity, the surface activity, or the protection of a ground installation requires the application of restrictions within that airspace.

No person may conduct aerial activities within active Class F restricted airspace unless permission has been obtained from the user agency. In some instances, the user agency may delegate a controlling agency the authority to approve access. In most cases, the controlling agency will be an ATC unit or an ANSP.

The User Agency is the civil or military agency or organization responsible for the activity for which the Class F airspace has been provided. It has the jurisdiction to authorize access to the airspace when it is classified restricted. The User Agency must be identified for Class F restricted airspace, and where possible, it should be identified for Class F advisory airspace.

There are two additional methods of restricting airspace.

- a. CAR 601.16 is designed to allow the Minister to issue a NOTAM to restrict flight around and over forest fire areas or areas where forest fire control operations are being conducted. The provisions of this section can be invoked quickly via NOTAM by Transport Canada.
- b. Section 5.1 of the *Aeronautics Act* allows the Minister to restrict flight in any airspace, for any purpose, by NOTAM. This authority is delegated by the Minister to cover specific situations, such as well fires, disaster areas, etc., for the purpose of ensuring safety of flight for air operations in support of the occurrence.

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

It should be noted that airspace that is restricted by invoking CAR 601.16 or Section 5.1 of the *Aeronautics Act* is *not* Class F restricted airspace; the airspace has not been *classified* in accordance with the airspace regulations. This distinction is important to those who are charged with the responsibility for restricting airspace, since their actions are governed by the provisions of the *Statutory Instruments Act*.

2.8.6.5 Joint Use Airspace

Joint-use airspace is Class F airspace within which operations may be authorized by the controlling agency when it is not being utilized by the user agency.

Class F restricted airspace should be available for use by nonparticipating aircraft when all or part of the airspace is not required for its designated purpose.

To ensure maximum utilization of restricted airspace, user agencies should be encouraged to make restricted airspace available for the conduct of operations or training of other agencies or commands on a joint-use basis.

An ATS unit may be designated to provide air traffic control or information service within the Class F airspace involved. A controlling agency will normally be assigned when there is joint use of the airspace.

2.8.6.6 NOTAM

It is permissible to designate Class F restricted airspace by NOTAM, if the following prerequisites are met:

- a. the area of restricted airspace is required for a specified period of time of relative short duration (i.e., several hours or days); and
- b. the appropriate NOTAM is issued at least 24 hours in advance of the area's activation.

2.8.7 Class G Airspace

Class G airspace is airspace that has not been designated Class A, B, C, D, E, or F and within which ATC has neither the authority nor responsibility for exercising control over air traffic.

However, ATS units do provide flight information and alerting services. The alerting service will automatically alert search and rescue authorities once an aircraft becomes overdue, which is normally determined from data contained in the flight plan or flight itinerary.

In effect, Class G is all uncontrolled domestic airspace.

Low-level air routes are contained within Class G airspace. They are basically the same as a low-level airway except that they extend upwards from the surface of the earth and are not controlled. The lateral dimensions are identical to that for a low-level airway.

2.9 PERFORMANCE-BASED NAVIGATION (PBN)**2.9.1 General**

Performance-based navigation (PBN) is not a stand-alone concept. Rather, along with communications, surveillance, and air traffic management (ATM), it is one of the four strategic enablers that support an overall airspace concept. An airspace concept may be described as a master plan

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

or vision for a particular section of airspace, which aims to improve safety, increase capacity and efficiency, and mitigate negative environmental impacts.

PBN is intended to enable more repeatable, reliable and predictable flight tracks as well as smaller route containment areas to increase operational efficiency. In the simplest form, it is RNAV based on performance requirements for aircraft operating along an ATS route, on an IAP or within designated airspace. Under the PBN concept, RNAV is defined as a method of navigation that permits aircraft operation on any desired flight path within the coverage of ground-based or space-based NAVAIDs or within the limits of the capability of self-contained aids (inertial navigation). Area navigation systems can take two forms: RNAV, which is the basic definition above, or required navigation performance (RNP), which has an additional functional requirement for on-board performance monitoring and alerting. The RNP system relies upon the capability of the on-board navigation system to monitor, in real time, the achieved navigation performance and to alert the flight crew when the specified minimum performance appropriate to a particular operation cannot be met. This additional functionality provided by RNP allows the flight crew to intervene and take appropriate mitigation actions if necessary. On-board performance monitoring and alerting allows RNP operations to provide an additional level of safety and capability over RNAV operations.

All future RNAV will identify performance requirements through the use of navigation specifications rather than defining required equipment of specific navigation sensors (VOR, ADF, etc.). These navigation specifications are expressed in terms of accuracy, integrity, availability, continuity, and functionality needed for the proposed operation.

Accuracy: In the context of PBN, accuracy is the capability of the navigation system to maintain the computed position within a specified distance (lateral navigation accuracy) of the actual position 95 percent of the time.

Integrity: Integrity is the level of confidence that can be placed in the information received from the navigation system. Normally defined as a percentage probability to satisfy the assurance condition (i.e. 10^{-5}), it includes the ability of an RNP system to provide timely and valid warnings to users when the system must not be used for the intended operation or phase of flight.

Availability: Availability is stated as a percentage of time the navigation system can perform its function. It should provide reliable navigation information and present it to the crew, autopilot or other system managing flight of the aircraft.

Continuity: Continuity refers to the ability of a navigation system to provide its service without interruption. It should do so with the specified level of accuracy and integrity throughout the intended period of operation, assuming that it was available at the start of the operation.

Functionality: A set of functions or capabilities associated with PBN operations. Examples could include course deviation scaling and radius to fix (RF) capability.

2.9.2 Key Elements of PBN

PBN consists of three main elements: NAVAID infrastructure, navigation specifications and navigation applications. These elements, described in detail further on, must be present to have a fully incorporated PBN concept.

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

2.9.2.1 *NAVAID Infrastructure*

The NAVAID infrastructure that contributes to an RNAV system may consist of ground-based, space-based or on-board NAVAIDs that support or provide positioning capabilities. System types are as follows:

- a. Ground infrastructure, which includes commissioned VORs and DMEs. (NDBs do not provide the specific range and azimuth information with accuracy necessary to be used in an RNAV system).
- b. Authorized GNSS space-based infrastructure (satellite constellations) such as: GPS, the European Union's Galileo, the Russian global navigation satellite system (GLONASS), etc.
- c. Satellite-based augmentation systems (SBAS) that correct for variance in the GNSS satellite signals in order to provide greater accuracy and/or signal quality, e.g. WAAS.
- d. GNSS ground-based augmentation systems (GBAS) that provide navigation and precision approach service in the vicinity of the host airport, e.g. local-area augmentation system (LAAS), GBAS landing system (GLS), etc.
- e. Certified INS or inertial reference units (IRU), which support on-board capability.

2.9.2.2 *Navigation Specifications*

A navigation specification is used as the basis for airworthiness and operational approval. It details the performance required of an RNAV or RNP system in terms of accuracy, integrity, availability, continuity, required navigation functionalities and NAVAIDs, and any requirements placed on the flight crew. Having a published navigation specification on Canadian routes and procedures will ensure compliance with common aircraft equipment and training that will result in assurance of track conformance. There are two main types of navigation specifications: RNAV and RNP.

An RNAV specification is based on an RNAV system and would be denoted by RNAV(X). An RNP navigation specification is based on an RNP system and is denoted by RNP(X).

In the examples above, "(X)" indicates the lateral navigation accuracy, in nautical miles, to be maintained 95 percent of the flight time by the population of aircraft operating within the airspace, route or procedure. For RNP specifications, it is also possible to have advanced RNP (A-RNP) and approach navigation specifications that cover all segments of an instrument approach. They are denoted as RNP APCH (RNP approach) or RNP AR APCH (RNP authorization required approach).

A navigation specification identifies not only a lateral accuracy figure but also functional and aircrew requirements. Therefore, certification for one type of navigation specification does not imply automatic qualification for a less stringent specification, and an RNP specification doesn't necessarily enable an RNAV specification.

ICAO has developed guidance on a range of navigation specifications. It is the responsibility of each State to determine which navigation specifications would be most applicable within their airspace concept with regards to current regulations and NAVAID infrastructure. For this reason it is

CA 2
AIRSPACE REQUIREMENTS AND PROCEDURES

important to note that what is needed to meet a navigation specification in one State may vary from that of another.

The following chart depicts all of the navigation specifications and their intended operational domain as outlined in Idahos *Performance-based Navigation (PBN) Manual* (Doc 9613).

2.9.2.3 *Navigation Application*

Navigation application is the application of a navigation specification and supporting NAVAID infrastructure to specific routes, procedures and/or defined airspace volumes.

Figure 2.11 — Navigation Specification Designations

NAVIGATION SPECIFICATIONS			
RNAV Specification		RNP Specifications	
Oceanic and Remote Navigation Applica-tions	Enroute and Terminal Navigation Applica-tions	Oceanic and Remote Navigation Applica-tions	Enroute and Terminal Navigation Applica-tions
RNAV 10*	RNAV 5 RNAV 2 RNAV 1	RNP 4 RNP 2	RNP 2 RNP 1 A-RNP RNP APCH RNP AR APCH RNP 0.3
*Formerly referred to as RNP 10			

2.9.3 *Navigation Specifications Expanded*

2.9.3.1 *RNAV 10*

RNAV 10 was historically designated as RNP 10. It requires aircraft be equipped with at least two independent long range navigation systems; any combination of INS/inertial reference unit (IRU) or GNSS meet the RNAV 10 requirements. During operations in airspace or on routes designated as RNAV 10, the lateral total system error must also be within ±10 NM for at least 95 percent of the total flight time. For normal operations, cross-track error/deviation should be limited to plus or minus one-half of the navigation accuracy associated with the route (i.e. 5 NM). Brief deviations from this standard (e.g. overshoots or undershoots) are allowable during and immediately after route turns, up to a maximum of one times the navigation (i.e. 10 NM).

Canadian RNAV 10 operations requirements are defined in Advisory Circular (AC) 700-006, *Required Navigation Performance 4 (RNP 4)* and *Required Navigation Performance 10 (RNP 10) Airspace*, and the associated Special Authorization RNP 10.

2.9.3.2 *RNAV 5*

RNAV 5 is an enroute navigation specification and may also be used for initial STAR or ending SID segments, where the leg segments are beyond 30 NM from an airport. RNAV 5 operations

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

are based on the use of RNAV equipment that automatically determines aircraft position in the horizontal plane using inputs from one or a combination of the following types of position sensors:

- VOR/DME
- DME/DME
- INS or IRS
- GNSS

VOR/DME- and DME/DME-based RNAV 5 have limited opportunities in Canadian airspace because of the required numbers and geometry of ground-based aids to provide robust infrastructure. Introduction of RNAV 5 in Canadian airspace applications is of low value since current RNP 5 airspace requirements already require performance that exceeds RNAV 5 when conducting RNAV.

Operational requirements are defined in Advisory Circular (AC) 700-015, *En Route Area Navigation Operations RNAV 5 (Formerly B-RNAV)*, and the associated Special Authorization RNAV 5.

2.9.3.3 RNAV 1 and RNAV 2

RNAV 1 and RNAV 2 operations are based on the use of the same aircraft receivers as those required for RNAV 5. Additional aircraft functionality and NAVAID infrastructure requirements are needed to meet the more demanding performance of RNAV 1 and RNAV 2. This navigation specification is applicable to all routes, inside or outside of controlled airspace, SIDs and STARs. It also applies to IAP leg segments up to the FAF. RNAV 1 and RNAV 2 routes are expected to be conducted in a surveillance environment with DCPC. In Canada, RNAV 1 has some potential for terminal RNAV use for SIDs and STARs in areas where multiple DME pairs are available.

Operational requirements are defined in Advisory Circular (AC) 700-019, *Terminal and En Route Area Navigation Operations (RNAV 1 and 2)*, and the associated Special Authorization RNAV 1 and RNAV 2.

2.9.3.4 RNP 4

RNP 4 is intended for oceanic or remote airspace where a robust ground-based navigation infrastructure is not available. Aircraft must have at least two fully serviceable independent long range navigation systems (LRNS) listed in the flight manual; both must be operational at the point of entry into RNP 4 airspace. Position integrity bounding can currently only be met using certified GNSS receivers. The GNSS receivers may be part of a stand-alone navigation system or one of the sensors in a multi-sensor system. Where GNSS is an input as part of a multi-sensor system, the aircraft's position source must use GNSS positions exclusively during RNP 4 operations.

Canadian operational requirements are defined in Advisory Circular (AC) 700-006, *Required Navigation Performance 4 (RNP 4) and Required Navigation Performance 10 (RNP 10) Airspace*, and the associated Special Authorization RNP 4.

2.9.3.5 RNP 2

RNP 2 is intended for enroute application, primarily in areas where there is sparse or no ground NAVAID infrastructure, limited or no ATS surveillance, and low- to medium-density traffic. Use of

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

RNP 2 in continental applications requires a lower continuity requirement than used in oceanic or remote applications. In oceanic or remote applications, the target traffic is primarily transport category aircraft operating at high altitude, whereas continental applications may include a significant percentage of other aircraft.

RNP 2 requires the use of certified GNSS receivers. Operators are required to have the means to predict the availability of GNSS fault detection (e.g. aircraft-based augmentation system ABAS RAIM) to support operations along an RNP 2 route. The *AIP Canada (ICAO)* (not published herein) will indicate when a prediction capability is required and an acceptable means to satisfy that requirement.

Operational requirements for RNP 2 (Continental) are defined in AC 700-38 — *Performance-based Navigation (PBN) — EnRoute* and the associated Special Authorization RNP 2 (Continental). RNP 2 (Oceanic/Remote) has additional requirements over those for RNP 2 Continental, but they have not yet been defined in a Canadian AC. A separate AC will be published when RNP 2 (Oceanic/Remote) operations are implemented in Canadian-controlled airspace.

2.9.3.6 RNP 1

The RNP 1 navigation specification is intended to be applied on SIDs and STARs within 30 NM of the airport where the surveillance services are limited or do not exist and/or a ground-based RNAV infrastructure is not practical. The STARs provide a means to connect the enroute structure to a variety of approach procedures, including RNP approach (RNP APCH), RNP authorization required approach (RNP AR APCH) and ILS. Application of RNP 1 enables the use of radius-to-fix (RF) leg segments in applications such as the STAR, transition to the approach or approach initial segments.

Position integrity bounding for RNP 1 can currently only be met using certified GNSS receivers. The GNSS receivers may be a part of a stand-alone navigation system or one of the sensors in a multi-sensor system. Where GNSS is an input as part of a multi-sensor system, the aircraft's position source must use GNSS positions exclusively during RNP 1 operations. During operations in airspace or on routes designated as RNP 1, the lateral total system error must be within ± 1 NM for 95 percent of the total flight time. For normal operations, crosstrack error/deviation should be limited to plus or minus one half of the navigation accuracy associated with the procedure. Brief deviations from this standard during and immediately after turns, up to a maximum of one times the navigation accuracy are allowable.

For RNP 1 routes, pilots must use a lateral deviation indicator, flight director, or autopilot in lateral navigation mode. Pilots of aircraft with a lateral deviation display must ensure that lateral deviation scaling is suitable for the navigation accuracy associated with the route/procedure.

Canadian RNP 1 operational requirements are defined in Advisory Circular (AC) 700-025, *Required Navigation Performance 1 (RNP 1)*, and the associated Special Authorization RNP 1.

2.9.3.7 RNP 0.3

RNP 0.3 was developed in response to the helicopter community's desire for narrower IFR obstacle-free areas to allow operations in obstacle-rich environments and to allow simultaneous, non-interfering operations in dense terminal airspace. While this specification has been defined pri-

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

marily for helicopter applications, it does not exclude the application to fixed-wing operations where demonstrated performance is sufficient to meet the functional and accuracy requirements of this specification for all phases of flight.

This specification requires the use of certified GNSS receivers; its implementation is not dependent on the availability of space-based augmentations systems (SBAS). DME/DME-based RNAV systems are not capable of consistently providing RNP 0.3 performance, and RNP 0.3 operations through application of DME/DME-based navigation is not currently viable. Operators are required to have the means to predict the availability of GNSS fault detection (e.g. RAIM) to support RNP 0.3 operations. The on-board RNP system, GNSS avionics, air navigation service provider (ANSP) or other entities may provide a prediction capability. The *AIP Canada (ICAO)* (not published herein) will indicate when a prediction capability is required and an acceptable means to satisfy that requirement. Owing to the high availability of RNP 0.3 performance available to SBAS receivers, prediction will not be required where the navigation equipment can make use of SBAS augmentation and the planned operation will be contained within the service volume of the SBAS signal.

Operational requirements are currently defined in ICAO's *Performance-based Navigation (PBN) Manual* (Doc 9613), Volume II, Part C, Chapter 7, but have not yet been defined in a Canadian Advisory Circular; therefore, no Special Authorization is available.

2.9.3.8 *Advanced RNP (A-RNP)*

This is the only navigation specification that enables operations under other associated navigation specifications. When advanced RNP (A-RNP) is certified, the following other navigation accuracy and functional requirements are met in navigation specifications: RNAV 5, RNAV 2, RNAV 1, RNP 2, RNP 1, and RNP APCH. Some other functional elements are optional, such as RNP scalability, higher continuity, fixed radius transitions (FRT), and BARO VNAV. However, radius to fix (RF) leg capabilities are a requirement.

A-RNP has a very broad operational application; for operation in oceanic or remote airspace, on the continental enroute structure, as well as on arrival and departure routes and approaches. Operations would rely solely on the integrity of the RNP system without a reversionary capability to conventional means of navigation since a conventional infrastructure may not be available. The advantage of utilizing a designation of A-RNP for a flight operation is the combined performance and functionality of a range of navigation specifications encompassing all phases of flight.

For further information on A-RNP, refer to ICAO's *Performance-based Navigation (PBN) Manual* (Doc 9613), Volume II, Part C, Chapter 4. Canadian operational approval of A-RNP is not currently in place; therefore, no Advisory Circular or Special Authorization has been issued.

2.9.3.9 *RNP Approach (RNP APCH)*

RNP approach (RNP APCH) is the ICAO navigation specification designation for procedures currently published in Canada as "RNAV (GNSS)" and authorized under Special Authorization RNP APCH. They include approach operations with minima designated as "LNAV", "LNAV/VNAV", "LP" and "LPV".

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

Currently, integrity bounding for an RNP APCH can only be met using certified GNSS receivers. The GNSS receivers may be part of a stand-alone navigation system or one of the sensors in a multi-sensor system.

Canadian specific RNP APCH requirements are published in Advisory Circular (AC) 700-023, *Required Navigation Performance Approach (RNP APCH)*, and the associated Special Authorization RNP APCH.

2.9.3.10 RNP Authorization Required Approach (RNP AR APCH)

RNP authorization required approach (RNP AR APCH) procedures can be built with various levels of RNP lateral containment values on the initial, intermediate, final and missed approach segments. There are increasingly demanding aircraft certifications and operational approvals required when RNP values lower than 0.3 NM are applied in any of the segments. These approaches will be published in pertinent publications as “RNAV (RNP)”.

As with all the other RNP navigation specifications, RNP AR APCH position integrity bounding can only be met by utilizing certified GNSS receivers. There are numerous other aircraft equipment and functional requirements needed to meet the more demanding performance requirements. They can be found in Advisory Circular (AC) 700-024, *Required Navigation Performance Authorization Required Approach (RNP AR APCH)*, and Special Authorization RNP AR APCH.

2.9.4 Fixed Radius Paths

Typically, with conventional navigation, turns had a large range of dispersion (some aircraft turned tight, others had wider turns) depending on aircraft speed, turn anticipation, bank angle and roll rate. Fixed radius paths standardize turns and provide a predictable, repeatable and accurate ground track throughout a turn. Using RNP, aircraft can have a smaller area of containment throughout a turn, allowing greater flexibility to design procedures that avoid terrain, noise sensitive areas, restricted airspace or other arrival paths to nearby airports in a complex airspace structure. There are two types of fixed radius paths that may be used: radius to fix path terminator (RF) and fixed radius transitions (FRT).

While complex flight paths can now be designed and displayed as the active route, the aircraft must have the capability to accurately follow the defined path. Pilots are familiar with flying turns at a constant airspeed and angle of bank which enables a circular flight path to be flown with reference to the air mass and are trained to manually compensate for the presence of wind if necessary. Pilots now need to understand that the RNP system will fly an exact circular flight path over the ground. Groundspeed and the angle of bank must be adjusted throughout the turn by the automatic flight control system to maintain that circular flight path and in some cases these may be limiting factors for maintaining the specified turn radius.

2.9.4.1 Radius to Fix (RF) Path Terminator

The RF path terminator, referred to as an RF leg, is a specific fixed-radius curved path in a terminal or approach procedure. An RF leg is defined by a constant radius originating from the center fix, the arc starting fix, the arc ending fix and the turn direction. Only RNP systems are capable of flying RF legs by providing precise and positive course guidance along a curved track, with the same containment value that would be achieved in a straight leg segment. In addition, the dis-

CA 2 AIRSPACE REQUIREMENTS AND PROCEDURES

tance travelled from beginning to end of the turn will remain constant for every aircraft. This allows longitudinal separation to be maintained throughout the turn for aircraft travelling at the same speed.

Operational approval to use RF legs in conjunction with other RNP navigation specifications can be found in Advisory Circular AC 700-027, *Radius to Fix (RF) Path Terminator*, and Special Authorization RF Leg. Additional authorization is not required for RNP AR APCH or A-RNP as RF capability is already mandatory in these two Special Authorizations.

2.9.4.2 Fixed Radius Transition (FRT)

A fixed radius transition (FRT) is used as an enabler to apply closer route spacing along turns in the enroute structure. An FRT is intended to define the transition between airways where separation is required in the turns. Having smaller containment areas in turns allows for higher traffic density with closer spaced routes. The RNP system supporting FRT is capable of providing the same track-keeping accuracy in the turn as in the straight line segment. An RNP system seamlessly joins associated route segments.

Operational approval is not currently available in Canada. For further information on FRTs reference ICAO's *Performance-based Navigation (PBN) Manual* (Doc 9613), Volume II, Part C, Appendix 2.

2.9.5 ICAO Flight Plan Completion

Pilots should review the planned route of flight to determine that RNAV/RNP requirements, the aircraft and the operator are approved for the desired route. PBN compliant aircraft should enter the appropriate equipment code in Item 10 of the ICAO flight plan. A corresponding indication of RNAV and/or RNP capabilities must be entered in Item 18.

2.9.6 Navigation Error Components

The inability to achieve the required lateral navigation accuracy may be due to navigation errors related to aircraft tracking and positioning. These errors produce a path that is offset horizontally from the desired path. The following are sources of error for RNAV systems:

Figure 2.12 — Lateral Navigation Errors

Where:

- Desired path is the path over the ground the aircraft is expected to fly.

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

- Defined path is reference path computed by flight plan management function of the RNAV system.
- Estimated position is provided by the NAV function of the RNAV system.
- True position is the aircraft's actual position over the ground.

Path definition error (PDE): The difference between desired and defined paths which reflects errors in the navigation database, computational errors in the RNAV system and display errors. PDE is usually very small and often assumed to be negligible.

Flight technical error (FTE): The difference between estimated position and defined path. It relates to the ability of an air crew or autopilot to fly along a defined path. Any display errors, such as a course deviation indicator (CDI) centering error, may cause FTE. FTE is usually the largest error component of the total system error (TSE).

Navigation system error (NSE): The difference between true and estimated position. The NSE is defined during navigation system certification.

Total system error (TSE): The difference between true position and desired position. This error is equal to the sum of the vectors of the PDE, FTE and NSE.

Any of the errors mentioned above would affect the ability of the aircraft to meet the required lateral navigation accuracy. If the on-board performance monitoring system cannot guarantee, with sufficient integrity, that the position meets the RNP defined in a navigation specification, an alert will be issued to the crew.

2.10 OTHER AIRSPACE DIVISIONS

Additional airspace divisions have been designated in order to increase safety or make allowances for the remote or mountainous regions within Canada. These divisions (or regions) are: Altimeter Setting Region, Standard Pressure Region and Designated Mountainous Region.

2.10.1 Altitude Reservation

An altitude reservation is an airspace of defined dimensions, within controlled airspace, reserved for the use of a civil or military agency during a specified period. An altitude reservation may be confined to a fixed area (stationary) or moving in relation to the aircraft that operates within it (moving). Information on the description of each altitude reservation is normally published by NOTAM. Civil altitude reservations are normally for a single aircraft while those for military use are normally for more than one aircraft.

Pilots should plan to avoid known altitude reservations. ATC will not clear an unauthorized flight into an active reservation. IFR and CVFR flights are provided with standard separation from altitude reservations.

2.10.2 Temporary Flight Restrictions — Forest Fires

In the interest of safe and efficient fire fighting operations, the Minister may issue a NOTAM restricting flights over a forest fire area to those operating at the request of the appropriate fire control authority (i.e., water bombers), or to those with written permission from the Minister.

The NOTAM would identify the following:

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

- a. the location and dimensions of the forest fire area;
- b. any airspace in which forest fire control operations are being conducted; and
- c. the length of time during which flights are restricted in the airspace.

No person shall operate an aircraft in the airspace below 3000 ft AGL within 5 NM of the limits of a forest fire area or as described in a NOTAM. (CARs 601.15, 601.16 and 601.17)

2.10.3 Flight Operations Over or in the Vicinity of Nuclear Power Plants

Pilots are reminded that overflights of nuclear power plants shall be carried out in accordance with the provisions of CAR 602.14(2).

Pilots should also be aware that loitering in the vicinity of, or circling, nuclear power plants should be avoided. Aircraft observed operating in this manner in the vicinity of nuclear power plants could be intercepted by government or law-enforcement aircraft, and escorted away from the facility to the nearest suitable airport to be interviewed by police authorities.

2.10.4 Military Operations Areas

Regular military training activity, such as basic or advanced flight training or routine operational training, is typically carried out in Class F advisory airspace. More intensive operational training is normally reserved for Class F restricted airspace. Some non-hazardous military activity can still require increased coordination with ATC, but these exercises may not require advisory or restricted airspace to be designated.

Military operations areas (MOA) consist of airspace of defined dimensions established to segregate certain military activities from IFR traffic and to identify for VFR traffic where these activities are conducted. ATC will not clear a non-participating IFR aircraft through an active MOA, unless appropriate IFR separation can be provided. There is no need for VFR aircraft to avoid flight into an MOA, but pilots should be alert for both large and small military aircraft that may be operating there at various altitudes and speeds.

MOAs can be designated in Class G airspace. User agencies and pilots operating in such MOAs should be aware that non-participating aircraft may legally operate under IFR or VFR without an ATC clearance in these MOAs.

MOAs will be published on relevant aeronautical charts.

2.11 ALTIMETER SETTING REGION

The altimeter setting region is an airspace of defined dimensions below 18,000 ft ASL (see CAR 602.35 and Figure 2.13) within which the following altimeter setting procedures apply:

Departure — Prior to takeoff, the pilot shall set the aircraft altimeter to the current altimeter setting of that airport or, if that altimeter setting is not available, to the elevation of the airport.

Enroute — During flight, the altimeter shall be set to the current altimeter setting of the nearest station along the route of flight or, where such stations are separated by more than 150 NM, the nearest station to the route of flight.

Arrival — When approaching the airport of intended landing, the altimeter shall be set to the current airport altimeter setting, if available.

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

2.12 STANDARD PRESSURE REGION

The standard pressure region includes all airspace over Canada at or above 18,000 ft ASL (the high level airspace), and all low level airspace that is outside of the lateral limits of the altimeter setting region (see Figure 2.13 and CAR 602.35). Within the standard pressure region the following flight procedures apply:

General — Except as otherwise indicated below, no person shall operate an aircraft within the standard pressure region unless the aircraft altimeter is set to standard pressure, which is 29.92 inches of mercury or 1013.2 mbs. (See Note)

Departure — Prior to take-off, the pilot shall set the aircraft altimeter to the current altimeter setting of that airport or, if the altimeter setting is not available, to the elevation of that airport. Immediately prior to reaching the flight level at which flight is to be conducted, the altimeter shall be set to standard pressure (29.92 inches of mercury or 1013.2 mbs). If the planned cruising flight level is above FL180, resetting the altimeter to 29.92 inches of mercury or 1013.2 mbs at 18,000 ft ASL is acceptable and meets the requirement of CAR 602.36.

Arrival — Prior to commencing descent with the intention to land, the altimeter shall be set to the current altimeter setting of the airport of intended landing, if available. However, if a holding procedure is conducted, the altimeter shall not be set to the current airport altimeter setting until immediately prior to descending below the lowest flight level at which the holding procedure is conducted. Pilots of aircraft descending from cruising flight levels above FL180 may reset altimeters to the current altimeter setting of the airport of intended landing when approaching FL180 provided no holding or cruise level flight below FL180 is to be made or anticipated.

Transition — CAR 602.37 — *Altimeter Setting and Operating Procedures in Transition between Regions*, specifies that except as authorized by ATC, aircraft progressing from one region to another shall make the change in the altimeter setting while within the standard pressure region prior to entering, or after leaving, the altimeter setting region. If the transition is to be made into the altimeter setting region while in level cruising flight, the pilot should obtain the current altimeter setting from the nearest station along the route of flight as far as practical before reaching the point at which the transition is to be made. When climbing from the altimeter setting region into the standard pressure region, pilots should set their altimeters to standard pressure (29.92 inches of mercury or 1013.2 mbs) immediately after entering the standard pressure region.

When descending into the altimeter setting region, pilots shall set their altimeters to the appropriate station altimeter setting immediately prior to descending into the altimeter setting region. Normally, the pilot will receive the appropriate altimeter setting as part of his ATC clearance prior to descent. If it is not incorporated in the clearance, it should be requested by the pilot.

NOTE: When an aircraft is operating in the standard pressure region with standard pressure set on the altimeter subscale, the term "flight level" is used in lieu of "altitude" to express its height. Flight level is always expressed in hundreds of feet. For example FL250 represents an altimeter indication of 25,000 ft; FL50, an indication of 5000 ft.

CA 2 AIRSPACE REQUIREMENTS AND PROCEDURES

Figure 2.13 — Altimeter Setting and Standard Pressure Regions

2.13 MOUNTAINOUS REGIONS

Designated mountainous regions are areas of defined lateral dimensions, specified in the *Designated Airspace Handbook*, above which special rules concerning minimum IFR altitudes (CAR 602.124) apply.

An aircraft, when operated in accordance with IFR within designated mountainous regions, but outside of areas for which minimum altitudes for IFR operations have been established (including minimum radar vectoring altitudes, MOCAs, transition altitudes, 100 NM safe altitudes, MSAs and GASAs), shall be flown at an altitude of at least 2000 feet above the highest obstacle within 5 NM of the aircraft in flight when in Areas 1 and 5, and at least 1500 feet above the highest obstacle within 5 NM when in Areas 2, 3 and 4. (See Figure 2.14.)

CA 2 AIRSPACE REQUIREMENTS AND PROCEDURES

As minimum enroute IFR altitudes have been established for designated airways and air routes, such minimum altitudes shall be applied when flying in accordance with IFR along airways or air routes within designated mountainous regions, except that aircraft should be operated at an altitude which is at least 1000 ft. higher than the minimum enroute IFR altitude, when there are large variations in temperature and/or pressure. (See ATC Instrument Flight Rules — Enroute Procedures para 8.6).

Figure 2.14 — Designated Mountainous Regions in Canada

**CA 2
AIRSPACE REQUIREMENTS AND PROCEDURES**

2.14 EMERGENCY COMMUNICATIONS AND SECURITY

The rules for operating within the Air Defence Identification Zone (ADIZ) are specified in CAR 602.145 — ADIZ, and are repeated in ATC Flight Planning para 3.9.

Figure 2.15 — Air Defense Identification Zone (ADIZ)

2.15 ADS-B SERVICES IN THE EDMONTON FIR

ADS-B service has expanded into oceanic and remote areas facilitated by a constellation of low earth orbit (LEO) satellites hosting ADS-B receivers. A satellite receives ADS-B data including

CA 2 AIRSPACE REQUIREMENTS AND PROCEDURES

position, velocity and altitude from aircraft, which is then routed through other satellites and down-linked to a satellite operations ground station. The expanded surveillance system will permit uninterrupted ATS surveillance for equipped aircraft operating in Northern Canadian Airspace in the Edmonton FIR.

As a result of the expanded surveillance coverage, surveillance separation standards are available for eligible aircraft using both VHF and CPDLC.

Figure 2.16 — Ground-based Automatic Dependent Surveillance-Broadcast Coverage

CA 2 AIRSPACE REQUIREMENTS AND PROCEDURES

Figure 2.17 — VHF Coverage

In areas where VHF voice communication is not available, surveillance separations are applied using CPDLC. To be eligible, aircraft must meet the following requirements:

- ADS-B, with dedicated 1090 MHz out capability with extended squitter (ES)
- Specifications for RNP 4
- Specifications of RCP 240

ATS systems use Field 10 (Equipment) of the standard ICAO flight plan to identify an aircraft's data link and navigation capabilities. Operators should insert the following items into the ICAO flight plan (as per the 2012 flight plan format) for FANS 1/A or equivalent aircraft:

- Field 10a (Radio communication, navigation and approach aid equipment and capabilities);
 - insert "J5" to indicate CPDLC FANS1/A SATCOM (Inmarsat) or "J7" to indicate CPDLC FANS1/A SATCOM (Iridium) data link equipment. To be eligible for the space-based ADS-B

CA 2 AIRSPACE REQUIREMENTS AND PROCEDURES

with CPDLC separations, flights must maintain an active J5/J7 connection. Edmonton ACC will monitor all active datalink connections to ensure compliance; and

- insert “P2” to indicate RCP 240 approval.
- Field 10b (Surveillance equipment and capabilities);
- insert “D1” to indicate ADS with FANS1/A capabilities; and
 - B1 or B2 to indicate ADS-B.
- Field 18 (Other Information): insert the characters “PBN/L1” for RNP4.

Figure 2.17 — ATS Surveillance Without VHF Coverage (CPDLC)

Flight crews are expected to comply with normal non-surveillance procedures, which include position reports via voice or ADS-C, and all other operator-specific procedures currently used.

2.15.1 Service Limitations North of 72° North

In Edmonton FIR, Inmarsat satellite coverage has limitations in the north, so flights operating only with Inmarsat equipment may experience unreliability north of 72° North (N). There is no Inmarsat satellite coverage north of 80° N, so flights will not be able to use satellite voice communications (SATVOICE) services in this area using Inmarsat. Iridium SATVOICE services are available north

CA 2 AIRSPACE REQUIREMENTS AND PROCEDURES

of 80° N. Operators of aircraft that are equipped with both Inmarsat and Iridium modems should ensure that they switch to the Iridium system before operating north of 72° N.

Based on these service area limitations, operators are advised that Iridium-equipped flights (J7 in the ICAO flight plan) will be eligible for the space-based ADS-B with CPDLC separations in the entirety of the Edmonton FIR. For flights that are Inmarsat only (J5 in the ICAO flight plan), the separation would be available only within Inmarsat coverage.

In addition to expanded surveillance coverage and reduced separations, *Aireon ALERT Aircraft Locating Emergency Response Tracking* is now in operation. ALERT is a free global aircraft tracking solution that captures ADS-B data available to be shared with appropriate registered SAR organizations, ANSPs, Aircraft Operators, and Regulators.

To register for Aireon ALERT, ANSPs, Aircraft Operators, Regulators and Search and Rescue refer to www.aireonalert.com.

2.16 **ADVANCED SURVEILLANCE ENHANCED PROCEDURAL SEPARATION STANDARDS (ASEPS) IN THE GANDER OCEANIC CONTROL AREA**

ADS-B service has expanded into oceanic and remote areas facilitated by a constellation of LEO satellites hosting ADS-B receivers. A satellite receives ADS-B data including position, velocity and altitude from aircraft, which is then routed through other satellites and down-linked to a satellite operations ground station. The expanded surveillance system will permit uninterrupted ATS surveillance for equipped aircraft before, during and after entry into the North Atlantic (NAT) Region.

As a result of the expanded surveillance coverage, reduced separation standards are available for eligible aircraft. In order to be eligible for the reduced standards, aircraft must meet the following requirements:

- RVSM/HLA approval
- ADS-B equipped, with dedicated 1,090 MHz out capability
- Specifications for RNP 4
- Specifications of RCP 240 and RSP 180

ATS systems use Field 10 (Equipment) of the standard ICAO flight plan to identify an aircraft's data link and navigation capabilities. To be eligible for the reduced separations, operators should insert the following items into the ICAO flight plan (as per the 2012 flight plan format) for FANS 1/A or equivalent aircraft:

- Field 10a (Radio communication, navigation and approach aid equipment and capabilities);
 - insert “J5” to indicate CPDLC FANS1/A SATCOM (Inmarsat) or “J7” to indicate CPDLC FANS1/A SATCOM (Iridium) data link equipment; and
 - insert “P2” to indicate RCP 240 approval.
- Field 10b (Surveillance equipment and capabilities);
 - insert “D1” to indicate ADS with FANS1/A capabilities; and

CA 2

AIRSPACE REQUIREMENTS AND PROCEDURES

- B1 or B2 to indicate ADS-B.
- Field 18 (Other Information); insert the characters “PBN/” followed by “L1” for RNP4 and SUR/RSP180.

Flight crews are expected to comply with normal non-surveillance procedures, which include position reports via voice or ADS-C, and all other operator specific procedures currently used.

In addition to expanded surveillance coverage and reduced separations, *Aireon ALERT Aircraft Locating Emergency Response Tracking* is now in operation. ALERT (Aircraft Locating and Emergency Response Tracking) is a free global aircraft tracking solution that captures ADS-B data available to be shared with appropriate registered SAR organizations, ANSPs, Aircraft Operators, and Regulators.

To register for Aireon ALERT, ANSPs, Aircraft Operators, Regulators and Search and Rescue refer to www.aireonalert.com.

CA 3 FLIGHT PLANNING

SECTION 3

3.1 GENERAL

The flight planning requirements contained in this section are based, in part, on the *Canadian Aviation Regulations* (CAR), Part VI, General Operating and Flight Rules.

The pilot-in-command shall, before commencing a flight, be familiar with the available information that is appropriate to the intended flight (CAR 602.71).

The pilot-in-command of an aircraft shall, before commencing a flight, be familiar with the available weather information that is appropriate to the intended flight (CAR 602.72). Pilots should refer to the MET Section for aviation weather information.

3.2 PILOT BRIEFING SERVICE

The pilot briefing service is provided by FICs to assist pilots at the pre-flight planning stage and for information updates while enroute. Pilot requests for initial briefings while airborne are not encouraged because this practice leads to frequency congestion.

The telephone numbers of NAV CANADA FICs are found in Meteorology and Airport Directory. Long distance phone calls can be made to an FIC toll-free at 1-866-WXBRIEF (1-866-992-7433). A call to this number is routed to the FIC that serves the area from which the call originates. A call to 1-866-GOMÉTÉO (1-866-466-3836) is routed to the Québec FIC for the provision of bilingual service. A specific FIC may be contacted at the number shown in Meteorology. Collect calls from pilots are accepted at all FICs.

When requesting a briefing, identify yourself as a pilot; provide the aircraft identification and the following:

- a. type of flight (VFR, IFR, CVFR, composite) planned;
- b. type of aircraft;
- c. airport of departure and estimated time of departure (ETD);
- d. destination airport and estimated elapsed time (EET);
- e. planned cruising level(s) or altitude(s);
- f. route to be flown and estimated times of arrival at, and departure from, any intermediate airport(s);
- g. alternate airport, if appropriate;
- h. type of meteorological information requested, i.e. whether a briefing or consultation; and
- i. information already on hand, if any.

The flight service specialist requires this information to tailor the briefing to the planned flight and the needs of the pilot. The flight service specialist may omit information normally provided in a briefing if the pilot has indicated having the data on hand or requested the briefing be limited to specific information. The flight service specialist will terminate the briefing by soliciting flight plan information not already obtained at the beginning of the briefing and PIREP, if appropriate. (See ATC 3.15 for details concerning flight plan content).

CA 3 FLIGHT PLANNING

3.3 AERONAUTICAL INFORMATION

Aeronautical information (NOTAM, RSC, CRFI, flow control, etc.) is available at ATS units and at certain operations offices. Aeronautical information is routinely provided by FICs during a pilot briefing and upon request in FISE. Telephone numbers and RCO frequencies for all FICs are listed in the AIRPORT DIRECTORY — CANADA.

Canadian domestic NOTAMs are disseminated via the aeronautical fixed service (AFS) and stored electronically in accordance with a NOTAM series concept. NOTAMs are further divided as aerodrome NOTAM and flight information region (FIR) NOTAM in accordance with the subject and impact. Before commencing a flight, pilots must ensure that each pertinent NOTAM series and type has been reviewed, so that they are familiar with all appropriate NOTAMs for the intended flight.

All Canadian NOTAMs, with the exception of NOTAMJ, are composed and disseminated in the International Civil Aviation Organization (ICAO) format. Canadian NOTAM series have different distribution lists and dissemination categories.

3.4 WEIGHT AND BALANCE CONTROL

3.4.1 Definitions

The following definitions and abbreviations are used in weight and balance control:

- a. **Actual Weight** is the weight, when referenced to passenger weight, derived by the weighing of each passenger just prior to flight boarding, and then adding the allowances for personal clothing and carry-on baggage. Infants shall be weighed along with their accompanying adult. Where weighing scales are not available or serviceable, or the passenger refuses to be weighed, the following weights may be used in lieu of actual weight:
 1. **Volunteered Weight** is the weight obtained by asking the passenger for their weight, adding 4.5kg (10 lbs) to the disclosed weight, and then adding the allowances for personal clothing and carry-on baggage.
 2. **Estimated Weight** is the reasonable estimate of the passenger's weight made by the operator, where actual weight is not available and volunteered weight is either not provided or is deemed to be understated, to which allowances are then added for personal clothing and carry-on baggage.

NOTE: Personnel who board passengers should, with a reasonable degree of accuracy, be able to assess the validity of a passenger's volunteered weight, or estimate the weight, and shall include allowances for personal clothing and carry-on baggage. Where necessary, the volunteered weight should be appropriately increased so as to avoid gross inaccuracies.

- b. **Air Operator Segmented Weights** are the approved segmented weights derived by the air operator from statistically meaningful data using a methodology that is acceptable to the Minister. They may be used in lieu of TCCA published segmented weights and are applicable only to that air operator. Furthermore, the weights may be used only in circumstances consistent with those under which the survey was conducted.

CA 3 FLIGHT PLANNING

c. **Air Operator Standard Weights** are the approved standard weights derived by the air operator from statistically computed data in accordance with procedures that are acceptable to the Minister. They may be used in lieu of the standard weights published by TCCA and are applicable only to that air operator. Furthermore, the weights may be used only in circumstances consistent with those under which the survey was conducted.

d. **Basic Empty Weight** is the basic weight of the aircraft as determined in accordance with the aircraft flight manual (AFM).

e. **Carry-On Baggage** is the baggage that a passenger may carry on board. Based on the particular aircraft stowage limitations, the operator may limit the number, size, shape and weight of the carry-on baggage to enable it to be stowed under the passenger seat or in the storage compartment. Otherwise, the standard allowance is 5.9kg (13 lbs) of carry-on baggage per passenger and this remains constant throughout the year. Carry-on baggage weight shall be included in the weight of the passenger for the purpose of weight and balance calculation.

NOTE: The only circumstance under which the weight of the carry-on baggage may not be added to the weight of each passenger is when no carry-on baggage is permitted on the flight.

f. **Checked Baggage** is baggage that is individually checked in, weighed and placed in the cargo compartment of the aircraft. This includes baggage that is too large to be placed in the cabin of the aircraft and baggage that must be carried in the cargo compartment by regulation, security program, or company policy. For baggage checked plane-side, see the definition for plane-side loaded bag.

g. **Empty Weight** is the total weight of the following parts or contents, which are part of, or carried on board, the aircraft:

1. the airframe, including the rotor of a helicopter or gyroplane;
2. the power plant;
3. the fixed ballast;
4. the unusable fuel;
5. the maximum amount of normal operating fluids, including oil, power-plant coolant, hydraulic fluid, de-icing fluid and anti-icing fluid, but not including potable water, lavatory pre-charge fluid or fluid intended for injection into the engines; and
6. all of the installed equipment.

h. **Large Airplane** is an airplane with a maximum certificated take-off weight (MCTOW) of over 5700kg (12,566 lbs).

i. **Maximum Certificated Take-Off Weight (MCTOW)** is weight identified as such in an aircraft type certificate.

CA 3 FLIGHT PLANNING

- j. **Maximum Permissible Take-Off Weight or Maximum Take-Off Weight (MTOW)** is the maximum take-off weight for an aircraft as authorized by the aircraft's state of registry or as provided for in the aircraft type certificate.
- k. **On-Board Weight and Balance System** is a system that weighs the aircraft and its payload then calculates the CG using equipment on board the aircraft.
- l. **Operational Empty Weight** is the actual weight of the aircraft before loading for dispatch. The operational empty weight may include removable equipment, flight crew members and crew members (including baggage), oil, unusable fuel, as well as emergency equipment, and should be defined by the air operator. It does not include usable fuel and payload.
- m. **Operations Personnel** are the personnel whose duties and responsibilities involve maintenance, loading, unloading, dispatching, servicing, weight and balance, passenger escort, scheduling, de-icing, or working on the ramp. This also includes members of the flight crew and cabin crew, as well as anyone involved in the aircraft's operation.
- n. **Passenger** is a person, other than a crew member, who is carried on board an aircraft and who, for weight and balance control, is categorized as a(n):
 - 1. **Adult** — a person, regardless of sex, who is aged 12 years or older and who may be subcategorized as male or female;
 - 2. **Child** — a person (male or female) who is between two to less than 12 years of age; or
 - 3. **Infant** — a baby who is less than two years of age.
- o. **Personal Clothing Allowance** is the weight of personal clothing that a passenger carries on board the aircraft, which is standardized as 3.6kg (8 lbs) for summer and 6.4kg (14 lbs) for winter and must be added to the passenger's weight for the purpose of weight and balance calculation.
- p. **Plane-Side Loaded Bag** is any bag or item that is placed at the door or steps of an aircraft because it cannot be accommodated as carry-on baggage and that is subsequently placed in the aircraft cargo compartment or cargo bin.
- q. **Segmented Weights** are the statistically derived average adult (male or female) passenger weights modified by appropriate standard deviations so as to be representative of small passenger groups and provide a predetermined degree of confidence and accuracy (tolerance) that the actual weight of the passenger group will not exceed the weight calculated by using segmented weight values. The segmented weight table identifies weight values that are modified to cater for variations in aircraft passenger seating capacity and include personal clothing and carry-on baggage allowances. In the Canadian context, segmented weights are applicable for aircraft that are certificated with a passenger seating capacity of 5 or more and are operated under Subpart 703 of the CARs.

NOTE: Segmented weights should be used where actual weights, volunteered weights or estimated weights are not available or cannot be used.

CA 3 FLIGHT PLANNING

- r. **Small Aircraft** is an aircraft with a maximum permissible take-off weight of 5700kg (12,566 lbs) or less, or a helicopter with a maximum permissible take-off weight of 2730kg (6018 lbs) or less.
- s. **Standard Weights** are the weights published by TCCA as standard average passenger weights, including personal clothing and carry-on baggage allowances, for use in weight and balance calculations that do not involve actual weighing.

3.4.2 Weight Control

Pilots must recognize the effect of weight and balance on the performance and handling of aircraft, particularly in combination with performance-reducing factors, such as contaminated runways, aircraft icing, degraded engine performance, severe or uncoordinated maneuvers, turbulence, high ambient temperatures and emergency situations.

It is mandatory to calculate weight and balance accurately for every flight and ensure that they are within the aircraft's permissible limits in order to comply with the aircraft airworthiness certificate and conform to the regulations. Before the aircraft takes off, it is important that the PIC of the aircraft ensure that the load carried by the aircraft is of an appropriate weight; the weight must be distributed and secured in such a way that it may be carried safely on the intended flight. If weight and CG (balance) limitations are not observed, then the pilot has failed to comply with a legal condition for the operation of the aircraft and the airworthiness certificate is nullified.

It must be recognized that with many four- and six-seat aircraft, it is not possible to fill all the seats, use the maximum baggage allowance, fill all the fuel tanks and still remain within the approved weight and CG limitations.

Estimating baggage weight can result in gross inaccuracies. If it is possible that the aircraft is operating close to its MTOW, the baggage must be weighed. Even a pocket-sized spring balance can be used as a handy standby if weighing scales are not available. This reduces the risk involved in guesswork. Note that on some aircraft, restrictions are placed on rear-seat occupancy if the maximum baggage allowance is used. When the aircraft is carrying freight, check for discrepancies with the declared weight. Ensure the weight per unit area limitation on the baggage compartment floor is not exceeded. It is critical to ensure that the baggage/freight is properly stowed, cannot move during flight, and does not obstruct exits or access to emergency equipment. If the aircraft is suspected to be operating anywhere close to its maximum weight, passengers must be weighed. The risk of embarrassment is not a reason for risking safety or crossing weight limits. It is important to remember that a passenger's weight is not his or her stripped weight, but must include personal clothing and carry-on baggage allowances.

Fuel is supplied in pounds, kilograms, liters or gallons. Pilots should note which unit is being used and calculate the fuel weight accordingly. Incorrect conversion could be hazardous in terms of endurance and fuel weight estimation.

3.4.3 Balance

Balance refers to the location of the CG along the longitudinal axis of the aircraft. There are forward and aft limits established during certification flight testing; they are the maximum CG positions at which the longitudinal stability requirements can be met. If an aircraft is being operated

CA 3 FLIGHT PLANNING

outside these limits, its handling is either unsatisfactory or has not been investigated. The limits for each aircraft are contained in the pilot operating handbook and the AFM. The aircraft must not be flown outside these limits.

In many aircraft, there is significant CG movement as fuel is being consumed. Pilots should familiarize themselves with how this affects their aircraft.

3.4.4 Operational Requirements

It is the responsibility of the PIC of the aircraft to ensure that the weight and balance report of the flight accurately represents the actual load and that the actual load does not exceed the maximum allowable weight limits specified in the AFM for any phase of the flight.

The report may be prepared by the crew, another qualified person authorized by the company or by the operator of the aircraft.

Companies and operators may establish specific procedures with respect to preparing and retaining weight and balance documentation in order to meet regulatory requirements.

3.4.5 Computerized Systems

When a company or operator generates load data from a computerized weight and balance system, the integrity of the output data must be checked at regular intervals (preferably not greater than six months). The length of the intervals must be specified in the company operations manual.

There must be a means in place to identify the person inputting the data for the preparation of every load manifest. Moreover, the identity of that person must be verified and authenticated by the system and retained as required.

3.4.6 Segmented Weights

In practice, it was found that the use of standard passenger weights, regardless of aircraft size, increases the probability of overloading the aircraft when its passenger-carrying capacity decreases, and vice versa. For example, when the standard passenger weight is used for an aircraft certificated for 12 passengers, like the Twin Otter, the statistical probability of overloading the aircraft is as high as 25%, whereas when it is used for large passenger aircraft, like the Boeing 747, this probability diminishes to 0.0014%.

Furthermore, a single weight cannot account for the weight differences between men and women or for variations in aircraft seating capacity. To minimize the probability of overloading the aircraft, an alternative to standard passenger weights, called segmented weights, was implemented. Segmented weights are based on aircraft seating capacity and account for weight differences between men and women as well as for summer and winter variations.

Segmented weights are designed to guarantee a 95% confidence level that the actual total weight of passengers will not exceed the total weight of passengers obtained by using segmented weights by more than one percent. This is the benchmark of segmented weights for accuracy and reliability.

CA 3 FLIGHT PLANNING

3.4.6.1 *Derivation of Segmented Weights*

A specific methodology was used to calculate the precise values published in the segmented weight tables. TCCA's segmented weight tables are based on the Canadian Community Health Survey (CCHS), Cycle 2.1 (2003), which obtained large-scale weight data by interviewing some 130,000 Canadians. In addition, standard deviations of 16.8kg (37 lbs) for males and 14.6kg (32.2 lbs) for females were applied to obtain a revised average weight for each sex. These weights were further modified to account for specific aircraft seating capacity ranges so as to be representative of the highest average weight among all sample sizes for that range. A constant value of 5.9kg (13 lbs) for carry-on baggage was then added to the average adult (male/female) passenger weight and finally, two values were developed to account for seasonal variations in personal clothing — 3.6kg (8 lbs) for summer clothing and 6.4kg (14 lbs) for winter clothing. See Table 2 for finalized weight values.

3.4.7 **Computation of Passenger and Baggage Weights**

To compute passenger weight, the following methods are used: actual weights, standard weights and segmented weights.

NOTE: For aircraft with a passenger seating capacity of less than five, the use of actual weights provides the greatest accuracy in calculating the weight and balance of the aircraft; therefore, the use of standard or segmented passenger weights is not recommended.

- a. *Using Actual Weights* — In determining the actual weight, an air operator must weigh each passenger and must ensure that personal clothing and carry-on baggage are also weighed. The total of the person's weight, personal clothing and carry-on baggage would then be treated as the passenger's weight. Weighing should be conducted just before boarding (to minimize the chances of the passenger acquiring additional load just before boarding the aircraft); alternatively, the allowances for personal clothing and carry-on baggage can be added to a passenger's weight and the result can be used as the passenger's actual weight.

When a passenger refuses to be weighed, the air operator should ask the passenger to volunteer their weight (volunteered weight). If they refuse, the air operator should estimate the passenger's weight (estimated weight), ensuring in both cases that the allowances for personal clothing and carry-on baggage are included in the passenger's weight.

Personnel boarding passengers based on volunteered weights should be able to assess the validity of the disclosed weight. If a volunteered weight is deemed to be significantly inaccurate, personnel should use good judgment to make a reasonably accurate estimate. Similarly, estimating passenger weight must be done with a reasonable degree of accuracy. Due diligence should be exercised to ensure that passenger weights used to calculate the passenger and baggage load accurately reflect the actual weight to be carried on any given flight.

- b. *Using Standard Weights* — The weight of each passenger is calculated using standard weights published by TCCA or established by the air operator. The standard weights include the standardized allowances for personal clothing and carry-on baggage. See Tables 1 and 3 for standard weights.

CA 3 FLIGHT PLANNING

- c. *Using Segmented Weights* — Segmented weights should be used only when actual weights, volunteered weights, and estimated weights are not available or cannot be implemented. Air operators are prohibited from using standard weights for airplanes operated under Subpart 703 of the CARs that also have a certificated passenger seating capacity of five or more passengers. Instead, it is recommended that they use either actual weights or the segmented weights that are published by TCCA or established by the air operator.

When using the segmented weight table (Table 2), an air operator must follow these steps:

1. Step 1: Under the column titled Maximum Certificated Passenger Seating Capacity, select the row that represents the certificated seating capacity of the intended aircraft.
2. Step 2: Under the column that represents the season, select winter or summer.
3. Step 3: Depending on the aircraft capacity and seasons selected in Steps 1 and 2, use the weight values identified in the intersecting cells for the weights of males and females. When changing the aircraft, Steps 1 to 3 have to be repeated.
4. Step 4: Multiply the individual male/female weight identified in Step 3 by the number of male/female passengers on board, and the total of these weights will be the weight of the passenger load for that particular flight.

NOTE 1: Actual weights should be used on any flight identified as carrying a significant number of passengers whose weight or number of carry-on baggage is deemed to be in excess of those specified in the segmented weights published by TCCA or established by the air operator.

NOTE 2: The only circumstance under which the weight of carry-on baggage may not be added to the weight of each passenger is when no carry-on baggage is permitted on the flight.

- d. *Weight of Children and Infants* — Each child should be weighed, or their weight should be included at the standard rate. Infants should be weighed with the accompanying adult. When an infant's weight is over 10% of the adult passenger's weight, the infant's weight should be included separately at the rate of 13.6kg (30 lbs) per infant. Infants occupying separate seats should be treated as children for the purpose of weight and balance calculation, and their weight should be included at the standard rate per child. See Table 3 for standard weights of children and infants.
- e. *Checked Baggage and Cargo* — The air operator must use the actual weight of checked baggage and cargo.

Table 1 — Standard Weights of Passengers Aged 12 Years or Older

Summer		Winter
93.4kg or 206 lbs	Males (12 years and up)	96.2kg or 212 lbs
78.1kg or 175 lbs	Females (12 years and up)	80.7kg or 181 lbs
93.4kg or 206 lbs	Gender X (12 years and up)	96.2kg or 212 lbs

Summer		Winter
34kg or 75 lbs	Children 2–11 years	34kg or 75 lbs
13.6kg or 30 lbs	Infants 0 to less than 2 years	13.6kg or 30 lbs

3.4.8 Fuel and Oil Weights

Fuel and oil weights were obtained from the Canadian Government Standards Bureau specifications. It should be remembered that the capacity of tanks is often expressed in U.S. gallons. The standard weights of fuel and oil are provided in Tables 4, 5 and 6.

NOTE: The weights shown are for the maximum density at the various temperatures. The actual fuel weight for specific conditions can usually be obtained from the dealer supplying the fuel. Conversion factors for liters to imperial gallons and kilograms to pounds are found in TABLE AND CODES — Reference Tables.

3.5 FLIGHT PLANS AND FLIGHT ITINERARIES

3.5.1 When Required

CAR 602.73 states that no pilot-in-command shall operate an aircraft in VFR flight unless a VFR flight plan or a VFR flight itinerary has been filed, except where the flight is conducted within 25 nautical miles of the departure airport.

No pilot-in-command shall operate an aircraft in IFR flight unless an IFR flight plan has been filed. A pilot-in-command may file an IFR flight itinerary instead of an IFR flight plan where:

CA 3 FLIGHT PLANNING

- a. the flight is conducted in part or in whole outside controlled airspace; or
- b. facilities are inadequate to permit the communication of flight plan information to an air traffic control unit, a flight service station or a community airport radio station.

Notwithstanding any of the requirements mentioned above, pilots are required to file a flight plan when operating between Canada and a foreign state.

3.5.2 Filing (CAR 602.75)

CAR 602.75

- (1) A flight plan shall be filed with an air traffic control unit, a flight service station or a community airport radio station.
- (2) A flight itinerary shall be filed with a responsible person, an air traffic control unit, a flight service station, or a community airport radio station.
- (3) A flight plan or flight itinerary, shall be filed by
 - (a) sending, delivering or otherwise communicating the flight plan or flight itinerary or the information contained therein; and
 - (b) receiving acknowledgement that the flight plan or flight itinerary or the information contained therein has been received.

A “responsible person” means an individual who has agreed with the person who has filed a flight itinerary to ensure that, if the aircraft is overdue, the following are notified in the manner prescribed in this Section:

- a. an ATC unit, a FSS or a community airport radio station; or
- b. a Rescue Coordination Center.

NOTE 1: The notification requires the flight itinerary information.

NOTE 2: The expression flight service station used in the regulation includes a FIC. Flight plan information should be filed with an FIC, where complete briefing information is available. An IFR flight plan should be submitted to the flight planning section of an ACC.

The timely filing of IFR flight plans or flight itineraries is essential to allow air traffic control personnel time to extract and record the relevant content, correlate these new data with available information on other traffic under control, coordinate as necessary, and determine how the flight may best be integrated with the other traffic.

Accordingly, in order to assist ATS in improving the service provided and to allow for sufficient time for input into the ATS data processing system, pilots are encouraged to file IFR flight plans or flight itineraries as early as practicable, preferably at least 30 min prior to their proposed departure time. Pilots are expected to depart in accordance with the flight planned estimated time of departure (ETD). Some delay could be experienced if an IFR clearance is required less than 30 min after filing. It is also important that ATS be informed of the circumstances if commencement of an IFR flight is to be delayed. IFR flight itineraries are limited to one departure from and one

CA 3 FLIGHT PLANNING

entry into controlled airspace; multiple exits and entries into controlled airspace will not be accepted by ATS.

3.5.3 Flight Plan Requirements — Flights Between Canada and a Foreign State

A VFR or IFR flight plan must be filed prior to conducting any flight between Canada and a foreign state. If the flight is to any country other than the U.S., an ICAO flight plan must be filed. ATS must not accept flight itineraries, composite flight plans, or CVFR flight plans for flights between Canada and the U.S.

ADCUS notification is no longer accepted on flight plans for transborder flights departing from Canada to the U.S. or from the U.S. to Canada. Pilots are required to file a flight plan to an acceptable customs destination in the U.S. and are also required to contact U.S. Customs and Border Protection (CBP) to make customs arrangements prior to their flight. Failure to do so may subject the pilot to a penalty.

3.5.4 Opening a VFR Flight Plan or Flight Itinerary

A VFR flight plan or flight itinerary should normally be opened with a control tower, a flight service station or a community airport radio station (CARS) upon departure to activate the alerting service. The pilot is responsible for extending or cancelling the flight plan or flight itinerary if the flight is delayed or cancelled. If an extension or cancellation is not received by the proposed time of departure, the responsible ATS unit will activate the flight plan or flight itinerary, using the ETD as the actual time of departure (ATD).

3.6 CHANGES TO THE INFORMATION IN A FLIGHT PLAN OR FLIGHT ITINERARY

Since control and alerting services are based primarily on information provided by the pilot, it is essential that modifications to flight plans and flight itineraries be communicated to an air traffic control unit, an FIC, a community airport radio station or, as applicable, a responsible person concerned as soon as practicable.

3.6.1 VFR Flight Plan or Flight Itinerary

CAR 602.76(3) and (4) specify that a pilot “shall notify as soon as practicable an air traffic control unit, a flight service station, a community airport radio station or the responsible person” of any change to:

- a. the route of flight,
- b. the duration of the flight; or
- c. the destination airport.

3.6.2 IFR Flight Plan or Flight Itinerary

CAR 602.76(1) and (2) specify that a pilot shall notify as soon as practicable an air traffic control unit, a flight service station, a community airport radio station or a responsible person, as the case may be, of any change to:

- a. the cruising altitude or cruising flight level,

CA 3 FLIGHT PLANNING

- b. the route of flight;
- c. the destination airport;
- d. when in controlled airspace:
 - 1. the true airspeed at the cruising altitude or cruising level where the change intended is 5% or more of the true airspeed specified in the IFR flight plan; or
 - 2. the Mach number, where the change intended is 0.01 or more of the Mach number that has been included in the air traffic control clearance.

Where the flight is being conducted in controlled airspace, the pilot shall receive an air traffic control clearance before making the intended change.

3.7 COMPOSITE FLIGHT PLAN OR FLIGHT ITINERARY — VFR AND IFR

A composite flight plan or flight itinerary may be filed that describes part(s) of the route as operating under VFR and part(s) of the route as operating under IFR. All rules governing VFR or IFR apply to that portion of the route of flight. A composite flight plan or flight itinerary shall not be filed for an aircraft that will enter airspace controlled by the FAA, including Canadian Domestic Airspace delegated to the FAA, as composite data cannot be correctly processed between NAV CANADA and FAA systems.

A pilot who files IFR for the first part of a flight and VFR for the next part will be cleared by ATC to the point within controlled airspace at which the IFR part of the flight ends. A pilot who files VFR for the first part of a flight and IFR for the next part are expected to contact the appropriate ATC unit for clearance prior to approaching the point where the IFR portion of the flight commences. If direct contact with an ATC unit is not possible, the pilot may request the ATC clearance through an FIC. It is important that the flight continue under VFR conditions until appropriate IFR clearance within controlled airspace is issued by ATC and acknowledged by the pilot.

3.8 DEFENCE VFR FLIGHT PLANS AND DEFENCE FLIGHT ITINERARIES (CAR 602.145)

CAR 602.145 outlines the requirements when operating into or within the Air Defence Identification Zone (ADIZ). In order to ensure that the Air Traffic System (ATS) is aware that VFR flights will be operating into or within the ADIZ, ATS requires that pilots file a Defence Flight Plan or Flight Itinerary as depicted at ATC 3.15.2.

CAR 602.145 ADIZ states:

602.145 ADIZ

- (1) This section applies to aircraft before entering into and while operating within the ADIZ, the dimensions of which are specified on Jeppesen Enroute Charts.
- (2) Every flight plan or flight itinerary required to be filed pursuant to this Section shall be filed with an air traffic control unit, a flight service station or a community airport radio station.

CA 3 FLIGHT PLANNING

- (3) The pilot-in-command of an aircraft whose point of departure within the ADIZ or last point of departure before entering the ADIZ has facilities for the transmission of flight plan or flight itinerary information shall
- (a) before takeoff, file a defence flight plan or defence flight itinerary;
 - (b) in the case of a VFR aircraft where the point of departure is outside the ADIZ,
 - (i) indicate in the flight plan or flight itinerary the estimated time and point of ADIZ entry, and
 - (ii) as soon as possible after takeoff, communicate by radio to an air traffic control unit, a flight service station or a community airport radio station a position report of the aircraft's location, altitude, airport of departure and estimated time and point of ADIZ entry; and
 - (c) in the case of a VFR aircraft where the point of departure is within the ADIZ, as soon as possible after takeoff, communicate by radio to an air traffic control unit, a flight service station or a community airport radio station a position report of the aircraft's location, altitude and airport of departure.
- (4) The pilot-in-command of an aircraft whose point of departure within the ADIZ or last point of departure before entering the ADIZ does not have facilities for the transmission of flight plan or flight itinerary information shall
- (a) as soon as possible after takeoff, file by radio communication a flight plan or flight itinerary; and
 - (b) in the case of a VFR aircraft, indicate in the flight plan or flight itinerary the estimated time and point of ADIZ entry, if applicable.
- (5) The pilot-in-command of a VFR aircraft shall revise the estimated time and point of ADIZ entry and inform an air traffic control unit, a flight service station or a community airport radio station, when the aircraft is not expected to arrive
- (a) within plus or minus five minutes of the estimated time at
 - (i) a reporting point,
 - (ii) the point of ADIZ entry, or
 - (iii) the point of destination within the ADIZ; or
 - (b) within 20 nautical miles of
 - (i) the estimated point of ADIZ entry, or
 - (ii) the center line of the route of flight indicated in the flight plan or flight itinerary.

3.9 INTERMEDIATE STOPS

Intermediate stops may not be included in a single instrument flight rules (IFR) flight plan. A single visual flight rules (VFR) flight plan or an IFR or VFR flight itinerary including one or more intermediate stops enroute may be filed provided that:

CA 3 FLIGHT PLANNING

- a. for VFR flight plans, the stop will be of short duration (for purposes such as boarding passengers, refuelling, etc.);
- b. for IFR flight itineraries, the stop will be in uncontrolled airspace; and
- c. each intermediate stop is indicated by repeating the name of the stopping point and its duration in the "Route" section of the flight plan or flight itinerary. Record the duration of the stopover in hours and minutes with four consecutive digits.

EXAMPLE: CYXU 0045 CYXU.

You may include a phone number for the stopover in the "Remark" section of the flight plan or flight itinerary, if available, as this may be useful in case of search and rescue (SAR).

When intermediate stops are planned, the "Estimated Elapsed Time" must be calculated as the total time to the final destination, including the duration of the intermediate stops. It should be noted that SAR action would only be initiated at the specified SAR time or, in the event that a SAR time is not indicated, 60 minutes for a flight plan and 24 hours for a flight itinerary after the estimated time of arrival (ETA) at the final destination. Pilots who wish to have SAR action based on every leg of a flight should file one flight plan or flight itinerary for each stop.

3.9.1 Consecutive IFR Flight Plans

Consecutive IFR flight plans may be filed at the initial point of departure providing the following points are adhered to:

- a. initial point of departure and enroute stops must be in Canada except that one flight plan will be accepted for a departure point within United States controlled airspace;
- b. the sequence of stops will fall within one 24-hour period;
- c. the flight planning unit must be provided with at least the following items of information for each stage of the flight:
 - 1. point of departure,
 - 2. altitude,
 - 3. route,
 - 4. destination,
 - 5. proposed time of departure,
 - 6. estimated elapsed time,
 - 7. alternate,
 - 8. fuel on board, and, if required
 - (a) TAS,
 - (b) number of persons on board, and
 - (c) where an arrival report will be filed.

CA 3 FLIGHT PLANNING

3.10 CROSS COUNTRY INSTRUMENT TRAINING FLIGHTS

A cross country instrument training flight is one in which there are no intermediate stops and one or more instrument approaches are made enroute. For example, an aircraft departs airport A, completes a practice approach at airport B and either lands at destination airport C or returns to land at airport A.

The following apply:

- a. A single flight plan is filed.
- b. Those enroute locations at which instrument approaches and overshoots are requested shall be listed in the "Other Information" portion of the flight plan form, together with the estimated period of time to carry out each approach. In addition, the total enroute time should be included, including approaches and holds followed by the destination airport (i.e., REQ NDB RWY 32 AT B - 15 MIN 0230A).
- c. The estimated elapsed time (EET) of the flight plan form is NOT to include the estimated time to carry out approaches and holds at the enroute locations.
- d. ATC will normally clear aircraft to final destination.
- e. If it is not practicable to clear the aircraft to final destination or to assign an operationally suitable altitude with the initial clearance, a time or specific location for the aircraft to expect further clearance to the destination or to a higher altitude will be issued with the initial clearance.
- f. When an enroute approach clearance is requested, a missed approach clearance will be issued to the aircraft prior to the commencement of the approach.
- g. If traffic does not permit an approach, holding instructions will be issued to the aircraft if requested by the pilot.

3.11 CLOSING A FLIGHT PLAN

In order to comply with CAR 602.77, an arrival report for a flight plan shall be submitted to an ATC unit, a FSS (or an FIC) or a community airport radio station as soon as practicable after landing but not later than

- a. the search and rescue time specified in the flight plan; or
- b. where no search and rescue time is specified in the flight plan, one hour after the last reported estimated time of arrival.

A pilot who terminates a flight itinerary shall ensure that an arrival report is filed with an ATC unit, a FSS, (or an FIC) a community airport radio station or, where the flight itinerary was filed with a responsible person, the responsible person as soon as practicable after landing but not later than

- a. the search and rescue time specified in the flight itinerary; or
- b. where no search and rescue time was specified in the flight itinerary, 24 hours after the last reported estimated time of arrival.

CA 3 FLIGHT PLANNING

A pilot who terminates an IFR flight at an airport where there is an operating ATC unit, FSS or where RAAS is provided, is not required to file an arrival report unless requested to do so by the appropriate ATC unit or FSS.

When submitting an arrival report, the pilot should clearly indicate that he/she was operating on a flight plan or flight itinerary and wishes it to be closed. Failure to close a flight plan or flight itinerary will initiate SAR action. It should not be assumed that ATS personnel will automatically file arrival reports for VFR flights at locations served by control towers and FSSs or an RCO. Toll-free calls may be made to an ATS facility for this purpose.

3.11.1 Arrival Report

CAR 602.78 specifies that the contents of an arrival report for a flight plan or flight itinerary shall include:

- a. the aircraft registration mark, flight number or radio call sign;
- b. the type of flight plan or flight itinerary;
- c. the departure airport;
- d. the arrival airport, and
- e. the date and time of arrival.

3.11.2 Closing of a Flight Plan Itinerary Prior to Landing

A pilot, who conducts a flight in respect of which a flight plan or flight itinerary has been filed with an air traffic control unit, Flight Information Center, flight service station, or community airport radio station, has the option of closing the flight plan or flight itinerary with any of these agencies prior to landing.

The closing of a flight plan or flight itinerary prior to landing is considered as filing an arrival report, and as such, it will result in the termination of all altering services with respect to search and rescue notification.

When flying IFR in airspace under the jurisdiction of Canadian ATC, use of the phrase "Cancelling IFR" results in ATC discontinuing the provision of IFR separation, but ***it does not automatically close the flight plan or itinerary***. Therefore, altering service with regards to search and rescue notification is still active and is based upon the information submitted in the original flight plan or itinerary. Because the pilot is now flying in accordance with Visual Flight Rules (VFR), the flight plan or itinerary must either be closed prior to landing, or an arrival report filed after landing, with an air traffic control unit, a Flight Information Center, a flight service station or a community airport radio station.

When flying IFR in the U.S.A. or landing at a Canadian airport that underlies airspace delegated to the control of the FAA, use of the phrase "Cancelling IFR" results in ATC discontinuing the provision of IFR separation and also closes the flight plan or itinerary. Therefore, alerting service with regard to SAR notification is also terminated, unless the pilot files and activates a VFR flight plan.

**CA 3
FLIGHT PLANNING****3.12 FUEL REQUIREMENTS**

The fuel requirements contained in this section do not apply to gliders, balloons or ultra-light airplanes. (CAR 602.88)

In addition to VFR and IFR fuel requirements, every aircraft shall carry an amount of fuel that is sufficient to provide for

- a. taxiing and foreseeable delays prior to takeoff;
- b. meteorological conditions;
- c. foreseeable air traffic routings and traffic delays;
- d. landing at a suitable airport in the event of loss of cabin pressurization or, in the case of a multi-engined aircraft, failure of any engine, at the most critical point during the flight; and
- e. any other foreseeable conditions that could delay the landing of the aircraft.

3.12.1 VFR Flight

An aircraft operated in VFR flight shall carry an amount of fuel that is sufficient to allow the aircraft

- a. in the case of an aircraft other than a helicopter,
 1. when operated during the day, to fly to the destination airport and then to fly for 30 minutes at normal cruising speed, or
 2. when operated at night, to fly to the destination airport and then to fly for 45 minutes at normal cruising speed, or
- b. in the case of a helicopter, to fly to the destination airport and then to fly for 20 min. at normal speed.

3.12.2 IFR Flight

An aircraft operated in IFR flight shall carry an amount of fuel that is sufficient to allow the aircraft

- a. in the case of a propeller-driven airplane,
 1. where an alternate airport is specified in the flight plan or flight itinerary, to fly to and execute an approach and a missed approach at the destination airport, to fly to and land at the alternate airport, and then to fly for a period of 45 minutes, or
 2. where an alternate airport is not specified in the flight plan or flight itinerary, to fly to and execute an approach and a missed approach at the destination airport and then to fly for a period of 45 minutes; or
- b. in the case of a turbojet powered airplane or a helicopter,
 1. where an alternate airport is specified in the flight plan or flight itinerary, to fly to and execute an approach and a missed approach at the destination airport, to fly to and land at the alternate airport, and then to fly for a period of 30 minutes, or

CA 3 FLIGHT PLANNING

2. where an alternate airport is not specified in the flight plan or flight itinerary, to fly to and execute an approach and a missed approach at the destination airport and then to fly for a period of 30 minutes.

3.13 REQUIREMENTS FOR ALTERNATE AIRPORT — IFR FLIGHT

Except as otherwise authorized by the Minister in an air operator certificate or in a private operator certificate, no pilot-in-command shall operate an aircraft in IFR flight unless the IFR flight plan or IFR flight itinerary that has been filed for the flight includes an alternate airport having a landing area suitable for use by that aircraft. No pilot-in-command of an aircraft shall include an alternate airport in an IFR flight plan or IFR flight itinerary unless available weather information indicates that the ceiling and ground visibility at the alternate airport will, at the expected time of arrival, be at or above the alternate airport weather minima criteria specified on the Jeppesen Airport chart. (CAR 602.122 and 602.123)

Aerodrome forecasts (TAFs) that contain the terms BECMG, TEMPO, or PROB may be used to determine the weather suitability of an airport as an alternate, provided that:

- a. where conditions are forecast to improve, the forecast BECMG condition shall be considered to be applicable as of the end of the BECMG time period, and these conditions shall not be below the published alternate minima requirements for that airport; and
- b. where conditions are forecast to deteriorate, the forecast BECMG condition shall be considered to be applicable as of the start of the BECMG time period, and these conditions shall not be below the published alternate minima requirements for that airport; and
- c. the forecast TEMPO condition shall not be below the published alternate minima requirements for that airport; and
- d. the forecast PROB condition shall not be below the appropriate landing minima for that airport.

3.13.1 Alternate Airport Weather Minima Requirements

Authorized weather minima for alternate airports are to be determined using the information presented in the tables below. The minima derived for an alternate airport shall be consistent with aircraft performance, navigation equipment limitations, functioning navigation aids (conventional and satellite-based), type of weather forecast, runway to be used and compliance with subsection 605.18(j) of the Canadian Aviation Regulations.

In addition to the Alternate Weather Minima Requirements tables below, the following must be considered by the pilot-in-command for satellite-based approaches at an alternate airport:

– Credit may be taken for satellite-based approaches provided that:

- Predicted satellite outages have been taken into account. The pilot-in-command verifies that approach-level RAIM or WAAS integrity is expected to be available at the proposed ETA for any airport;
- For GPS TSO C129/C129a avionics, periodically during the flight, and at least once before the mid-point of the flight to the destination, the pilot-in-command verifies that approach level RAIM is expected to be available at the planned destination and/or alternate ETA;

**CA 3
FLIGHT PLANNING**

- Where a satellite-based approach is planned at both the destination and alternate, the airports are separated by a minimum of:
 - 75 NM where both airports are in either Nunavut, or north of 56 degrees North latitude in Quebec and Labrador
 - 100 NM where either or both airports are located anywhere else in Canada.
- For RNP Approach navigation specifications [procedure identification RNAV (GNSS) RWY XX]:
 - No credit may be taken for LPV or LP lines of minima;
 - Credit may be taken for LNAV/VNAV lines of minima when the aircraft is certified for barometric LNAV/VNAV; and
 - Credit may be taken for LNAV lines of minima.
- For RNP AR Approach navigation specifications [procedure identification RNAV (RNP) RWY XX]:
 - No credit may be taken by General Aviation operators;
 - Credit may be taken by Private and Commercial operators provided they have a valid operator authorization in accordance with their Private Operator Registration Document (PORD) or Aircraft Operating Certificate (AOC); and
 - Credit may be taken for RNP 0.30 lines of minima only.

ALTERNATE WEATHER MINIMA REQUIREMENTS	
FACILITIES AVAILABLE AT SUITABLE ALTERNATE	WEATHER REQUIREMENTS
TWO OR MORE USABLE PRECISION APPROACHES each providing straight-in minima to separate suitable runways	400-1 or 200-1/2 above lowest usable Height Above Touchdown (HAT) and visibility, whichever is greater.
ONE USABLE PRECISION APPROACH	600-2* or 300-1 above the lowest usable HAT and visibility, whichever is greater.
NON-PRECISION ONLY AVAILABLE	800-2* or 300-1 above the lowest usable HAT/HAA and visibility, whichever is greater.
NO IFR APPROACH AVAILABLE	Forecast weather must be no lower than 500 ft above a minimum IFR altitude that will permit a VFR approach and landing.

**CA 3
FLIGHT PLANNING**

ALTERNATE WEATHER MINIMA REQUIREMENTS	
FACILITIES AVAILABLE AT SUITABLE ALTERNATE	WEATHER REQUIREMENTS
FOR HELICOPTERS, where instrument approach procedures are available	Ceiling 200 ft above the minima for the approach to be flown, and visibility at least 1 SM, but never less than the minimum visibility for the approach to be flown.
* 600-2 and 800-2 , as appropriate, are considered to be <i>Standard Alternate Minima</i> . Should the selected alternate weather requirements meet the standard minima, then the following minima are also authorized:	

Alternate Airport Weather Minima Requirements

STANDARD ALTERNATE MINIMA		IF STANDARD IS APPLICABLE, THEN THE FOLLOWING MINIMA ARE ALSO AUTHORIZED	
CEILING	VISIBILITY	CEILING	VISIBILITY
600	2	700	1 1/2
		800	1
800	2	900	1 1/2
		1000	1

NOTE 1: These requirements are predicated upon the airport having an **AERODROME FORECAST (TAF)** available.

NOTE 2: Airports served with an **AERODROME ADVISORY** forecast may qualify as an alternate provided the forecast weather is no lower than 500 ft above the lowest usable **HAT/HAA** and the visibility is not less than 3 miles.

NOTE 3: Airports served with a **GRAPHIC AREA FORECAST (GFA)** may qualify as an alternate provided the forecast weather contains:

- a. no cloud lower than 1000 ft above the lowest usable **HAT/HAA**;
- b. no cumulonimbus; and
- c. visibility is not less than 3 miles.

NOTE 4: Ceiling minima are calculated by reference to the procedure **HAA** or **HAT**. Ceiling values in aviation forecasts are established in 100 ft increments. Up to 20 ft, use the lower 100 ft increment; above 20 ft, use the next higher 100 ft increment:

EXAMPLE: **HAA** 620 ft = ceiling value of 600 ft

EXAMPLE: **HAA** 621 ft = ceiling value of 700 ft

EXAMPLE: **HAT** 420 ft = ceiling value of 400 ft

CA 3 FLIGHT PLANNING

EXAMPLE: HAT 421 ft = ceiling value of 500 ft

NOTE 5: Calculated visibilities should not exceed 3 miles.

CAUTION: All heights specified in a GFA are ASL, unless otherwise indicated.

The emphasis of these criteria is placed upon the availability of the lowest usable landing HAT/HAA and visibility for an airport. In determining the lowest usable landing HAT/HAA and visibility, the pilot should consider:

- a. the operational availability of the ground navigational equipment by consulting NOTAM;
- b. the compatibility of the aircraft equipment with the ground navigational equipment;
- c. the forecast surface wind conditions could dictate the landing runway and associated approach minima;
- d. the operational applicability of terms BECMG, TEMPO, and PROB within the forecast (see paragraph 3.13 — REQUIREMENTS FOR ALTERNATE AIRPORT — IFR);
- e. all heights mentioned within a GFA are ASL heights, unless otherwise indicated, and the terrain elevation must be applied in order to determine the lowest forecast ceiling at a particular location; and
- f. alternate minima values determined from a previous flight operation may not be applicable to a subsequent flight operation.

Aerodrome Forecasts (TAF) that contain the terms BECMG, TEMPO or PROB may be used to determine the weather suitability of an airport as an alternate, provided that:

- where conditions are forecast to improve, the forecast BECMG condition shall be considered to be applicable as of the end of the BECMG time period, and these conditions shall not be below the published alternate minima requirements for that airport;
- where conditions are forecast to deteriorate, the forecast BECMG condition shall be considered to be applicable as of the start of the BECMG time period, and these conditions shall not be below the published alternate minima requirements for that airport;
- the forecast TEMPO condition shall not be below the published alternate minima requirements for that airport; and
- the forecast PROB condition shall not be below the appropriate landing minima for that airport.

3.14 COMPLETION OF CANADIAN FLIGHT PLANS AND FLIGHT ITINERARIES AND ICAO FLIGHT PLANS

3.14.1 General

The flight plan form is to be used for Canadian flight plans or flight itineraries and ICAO flight plans. Completion of the form is simply a matter of inserting the requested information in the appropriate boxes. The white boxes relate to required information for Canadian flight plans and for flight itineraries and for ICAO flight plans. The shaded boxes indicate the information which is applicable only to Canadian flight plans and flight itineraries.

**CA 3
FLIGHT PLANNING**

NOTE: A Canadian flight plan is used for flights from Canada to the United States.

3.14.2 Canadian

A Canadian flight plan/flight itinerary shall contain such information as is specified in the Jeppesen Canada ATC section. This includes:

- aircraft identification
- flight rules
- type of flight
- number of aircraft (if more than one)
- type of aircraft
- wake turbulence category
- equipment
- departure airport
- time of departure (UTC)-proposed/actual
- cruising speed
- altitude/level
- route
- destination airport
- (EET) enroute
- SAR time (not required for an ICAO flight plan)
- destination alternate airport(s)
- other information
- endurance (flight time in hours and minutes)
- total number of persons on board
- type of ELT (not required for an ICAO flight plan)
- survival equipment (type, jackets, dinghies)
- aircraft color and markings
- remarks (regarding other survival equipment)
- arrival report – where it will be filed (not required for an ICAO flight plan)
- name and number or address of person or company to be notified if SAR action is initiated (not required for an ICAO flight plan)
- pilot's name
- pilot's license number (Canadian pilot license only)

CA 3 FLIGHT PLANNING

3.14.3 ICAO

Flight plans for international flights originating in, or entering, Canada shall be filed in the ICAO format, as specified in ICAO Doc 4444—*Operations* 5-2 PANS-RAC (DOC 4444-RAC/501 Mil GPH 204 DOC FLIGHT INFO PUBLICATION).

For the purpose of flight planning, flights between Canada and the Continental United States are not classed as “international flights”.

3.14.4 Instructions for Completing the Form

- a. Adhere closely to the prescribed formats and manner of specifying data.

Commence inserting data in the first space provided. Where excess space is available, leave unused spaces blank.

All times should be indicated in UTC, using four digits.

Indicate all EETs using four digits (hours and minutes) for flight plans.

NOTE: Because EETs on a flight itinerary may include days as well as hours and minutes: insert the EET using six digits, if required.

The shaded area preceding Item 3 is to be completed by ATS and COM services, unless the responsibility for originating flight plan messages has been delegated.

NOTE: The term “airport” where used in the flight plan, is intended to also cover sites other than airports which may be used by certain types of aircraft, e.g., helicopters or balloons.

- b. Instructions for insertion of ATS data:

1. Complete Items 7 to 18 as indicated hereunder.
2. Complete Item 19 as well to facilitate alerting of SAR services.

NOTE: Item numbers on the form are not consecutive, as they correspond to Field Type numbers in ATS messages.

Use location indicators listed in ICAO Doc 7910—*Location Indicators*, and in FAA Order 7350.7—*Location Identifiers* (not published herein).

3.15 CONTENTS OF A FLIGHT PLAN AND FLIGHT ITINERARY

3.15.1 Item 7: Aircraft Identification (not exceeding seven alphanumeric characters and without hyphens or symbols)

Canadian:

Normally, this consists of the aircraft registration letters or the company designator followed by the flight number. Examples:

- Aircraft Registration: N123B, CGABC, 4XGUC
- Operating Agency and Flight Number: ACA123, KLM672
- Tactical Call Sign: BRUNO12, SWIFT45, RED1

CA 3 FLIGHT PLANNING

ICAO:

- a. the ICAO designator for the aircraft operating agency followed by the flight identification (e.g., KLM511, NGA213, JTR25) when in radiotelephony the call sign to be used by the aircraft will consist of the ICAO telephony designator for the operating agency followed by the flight identification (e.g., KLM511, NIGERIA213, JESTER25); or
- b. the nationality or common mark and registration mark of the aircraft (e.g., E1AKO, 4XBCD, N2567GA), when:
 1. in radiotelephony, the call sign to be used by the aircraft will consist of this identification alone (e.g., CGAJS), or will be preceded by the ICAO telephony designator for the aircraft operating agency (e.g., BLIZZARD CGAJS); or
 2. the aircraft is not equipped with radio.

NOTE 1: Standards for nationality, common and registration marks to be used are contained in ICAO Annex 7, Chapter 2.

NOTE 2: Provisions for the use of radiotelephony call signs are contained in Annex 10, Volume II, Chapter 5. ICAO designators and telephony designators for aircraft operating agencies are contained in Doc 8585, Designators for Aircraft Operating Agencies, Aeronautical Authorities and Services (not published herein).

3.15.2 Item 8: Flight Rules and Type of Flight

- a. **Flight Rules** (1 character) (ICAO and Canadian)

INSERT one of the following letters to denote the category of flight rules with which the pilot intends to comply:

- | | |
|---|--|
| I | if it is intended that the entire flight will be operated under IFR; |
| V | if it is intended that the entire flight will be operated under VFR; |
| Y | If the flight initially will be operated under IFR, followed by one or more subsequent changes of flight rules; or |
| Z | if the flight initially will be operated under VFR, followed by one or more subsequent changes of flight rules. |

If “Y” or “Z” is filed, specify, in the route section of the flight plan (Item 15), the point(s) where a change in flight rules is planned. Similarly, where there is more than one change in the type of flight rules, the code to be used is to reflect the first rule, i.e., use “Z” for VFR/IFR/VFR.

- b. **Type of Flight** (up to two characters, as applicable)

INSERT up to two of the following letters to denote the type of flight when so required by the appropriate ATS authority:

First character (Canadian only - as applicable):

CA 3 FLIGHT PLANNING

- C for Controlled VFR
- D for Defense Flight Plan
- E for the Defense Flight Itinerary
- F for Flight Itinerary

Second character (ICAO, as applicable):

- S for Scheduled Air Service
- N for Non-scheduled Air Transport Operation
- G for General Aviation
- M for Military
- X for other than the preceding categories

Specify the status of a flight following the indicator “STS” in Item 18, or when necessary to denote other reasons for specific handling by ATS, indicate the reason following the indicator “RMK/” in Item 18.

3.15.3 Item 9: Number and Type of Aircraft and Wake Turbulence Category

a. **Number of Aircraft** (1 or 2 characters)

Insert the number of aircraft, if more than one.

b. **Type of Aircraft** (2 to 4 characters)

Insert the appropriate ICAO aircraft type designator. If no such designator has been assigned, or in the case of formation flights comprising more than one type, insert “ZZZZ” and specify in Item 18 the number(s) and type(s) of aircraft preceded by “TYP/”.

c. **ICAO Wake Turbulence Category** (1 character)

- H — HEAVY, to indicate an aircraft type with a maximum certificated takeoff mass of 136,000kg (300,000 lbs) or more.
- M — MEDIUM, to indicate an aircraft type with a maximum certificated takeoff mass of less than 136,000kg (300,000 lbs), but more than 7000kg (15,500 lbs).
- L — LIGHT, to indicate an aircraft type with a maximum certificated takeoff mass of 7000kg (15,500 lbs) or less.

3.15.4 Item 10: Equipment (Canadian and ICAO)

Capabilities comprise the following elements:

- a. presence of relevant serviceable equipment on board the aircraft;
- b. equipment and capabilities commensurate with flight crew qualifications; and

**CA 3
FLIGHT PLANNING**

c. where applicable, authorization from the appropriate authority.

The communication (COM), navigation (NAV), approach aid and SSR equipment on board and its serviceability must be inserted by adding the appropriate suffixes. The first suffixes will denote the COM, NAV and approach aid equipment, followed by an oblique stroke, and another suffix to denote the SSR equipment:

3.15.4.1 *Radio Communication, Navigation and Approach Aid Equipment and Capabilities*

INSERT one letter as follows:

- N — if no COM, NAV or approach aid equipment for the route to be flown is carried, or the equipment is unserviceable; or,
- S — if standard COM, NAV and approach aid equipment for the route to be flown is carried and available (see NOTE 1).

Information on navigation capability is provided to ATC for clearance and routing purposes.

AND/OR INSERT one or more of the following letters to indicate the COM, NAV and approach aid equipment and capabilities available:

- | | |
|----|----------------------------------|
| A | GBAS landing system |
| B | LPV (APV with SBAS) |
| C | LORAN C |
| D | DME |
| E1 | FMC WPR ACARS |
| E2 | D-FIS ACARS |
| E3 | PDC ACARS |
| F | ADF |
| G | GNSS (see NOTE 2) |
| H | HF RTF |
| I | Inertial Navigation |
| J1 | CPDLC ATN VDL Mode (see NOTE 3) |
| J2 | CPDLC FANS 1/A HFDL |
| J3 | CPDLC FANS 1/A VDL Mode 4 |
| J4 | CPDLC FANS 1/A VDL Mode 2 |
| J5 | CPDLC FANS 1/A SATCOM (INMARSAT) |
| J6 | CPDLC FANS 1/A SATCOM (MTSTAT) |

CA 3 FLIGHT PLANNING

J7	CPDLC FANS 1/A SATCOM (Iridium)
K	MLS
L	ILS
M1	ATC RTF SATCOM (INMARSAT)
M2	ATC RTF (MTSAT)
M3	ATC RTF (Iridium)
O	VOR
P1–P9	Reserved for RCP
R	PBN approved (see NOTE 4)
T	TACAN
U	UHF RTF
V	VHF RTF
W	RVSM approved
X	MNPS approved
Y	VHF with 8.33 kHz channel spacing capability
Z	Other equipment carried or other capabilities (see NOTE 5)

Any alphanumeric characters not indicated above are reserved.

NOTE 1: If the letter “S” is used, standard equipment is considered to be VHF, RTF, VOR and ILS, unless another combination is prescribed by the appropriate ATS authority.

NOTE 2: ICAO: If the letter “G” is used, the types of external GNSS augmentation, if any, are specified in Item 18 following the indicator “NAV/” and separated by a space.

Canadian: When using the letter “G” on an IFR flight plan, the GNSS receiver must be approved in accordance with the requirements specified in AIP Canada (ICAO) AIC-16/08 (not published herein) or replacement. IFR-certified receivers are not mandatory for VFR flights. Pilots are encouraged to use the letter “G” on VFR flight plans when using any type of GNSS to assist VFR navigation.

NOTE 3: See RTCA/EUROCAE Interoperability Requirements Standard For ATN Baseline 1 (ATN B1 INTEROP Standard — DO-280B/ED-110B) (not published herein) for data link services, ATC clearance and information, ATC communications management, and ATC microphone check.

NOTE 4: If the letter “R” is used, the performance-based navigation levels that can be met are specified in Item 18 following the indicator “PBN/”. Guidance material on the application of performance-based navigation to a specific route segment, route or area is contained in the Performance-Based Navigation Manual (ICAO Doc 9613) (not published herein).

CA 3 FLIGHT PLANNING

NOTE 5: If the letter “Z” is used, specify in Item 18 the other equipment carried, or other capabilities, preceded by “COM/”, “NAV/” and/or “DAT/”, as appropriate.

3.15.4.2 Surveillance Equipment and Capabilities

INSERT “N” if no surveillance equipment for the route to be flown is carried, or the equipment is unserviceable, or

INSERT one or more of the following descriptors, to a maximum of 20 characters, to describe the serviceable surveillance equipment and/or capabilities on board:

SSR Modes A and C

- A Transponder — Mode A (4 digits — 4096 codes);
- C Transponder — Mode A (4 digits — 4096 codes) and Mode C

SSR Mode S

- E Transponder — Mode S, including aircraft identification, pressure-altitude and extended squitter (ADS-B) capability;
- H Transponder — Mode S, including aircraft identification, pressure-altitude and enhanced surveillance capability;
- I Transponder — Mode S, including aircraft identification, but no pressure-altitude capability;
- L Transponder — Mode S, including aircraft identification, pressure-altitude, extended squitter (ADS-B) and enhanced surveillance capability;
- P Transponder — Mode S, including pressure-altitude transmission, but no aircraft identification capability;
- S Transponder — Mode S, including both pressure-altitude and aircraft identification capability;
- X Transponder — Mode S with neither aircraft identification nor pressure-altitude capability.

NOTE: Enhanced surveillance capability is the ability of the aircraft to down-link aircraft-derived data via a Mode S transponder.

ADS-B

- B1 ADS-B with dedicated 1090 MHz ADS-B “out” capability;
- B2 ADS-B with dedicated 1090 MHz ADS-B “out” and “in” capability;
- U1 ADS-B “out” capability using UAT;
- U2 ADS-B “out” and “in” capability using UAT;
- V1 ADS-B “out” capability using VDL Mode 4;
- V2 ADS-B “out” and “in” capability using VDL Mode 4.

CA 3 FLIGHT PLANNING

ADS-C

D1 ADS-C with FANS 1/A capabilities;

G1 ADS-C with ATN capabilities.

Alphanumeric characters not indicated above are reserved.

Example: ADE3RV/HB2U2V2G1

NOTE: Additional surveillance application should be listed in Item 18 following the indicator "SUR".

3.15.5 Item 13: Departure Airport and Time

3.15.5.1 *Departure Airport (maximum four characters)*

ICAO:

INSERT the ICAO four-letter location indicator of the departure airport as specified in ICAO Doc 7910 — *Location Indicators* (not published herein); or

Canadian:

INSERT the four-character location indicator of the departure airport; or

Canadian and ICAO:

If no location indicator has been assigned:

INSERT "ZZZZ" and specify in Item 18 the name and location of the airport preceded by "DEP/"; or

INSERT the first point of the route or the marker radio beacon preceded by "DEP/", if the aircraft has not taken off from the airport.

3.15.5.2 *Time (maximum four characters)*

Indicate the hour and minutes in UTC.

NOTE: Pilots may file a flight plan or flight itinerary up to 24 hours in advance of the departure time.

3.15.6 Item 15: Cruising Speed, Altitude/Level and Route

Canadian:

NOTE:

- a. *On designated airways and air routes, IFR flights may be operated at the published MEA/MOCA except that in winter, when air temperatures may be much lower than those of the ICAO Standard Atmosphere (ISA), aircraft should be operated at an altitude which is at least 1000 feet higher than the published MEA/MOCA.*
- b. *Mandatory IFR routes, published in the Enroute Section, have been established to aid in the efficient and orderly management of air traffic between selected airports. Pilots are required to file these routes.*

CA 3
FLIGHT PLANNING

Canadian and ICAO:

INSERT

- the first cruising speed as described in a.,
- the first cruising level as described in b.,
- and the route description as described in c.

a. Cruising Speed (maximum 5 characters)

INSERT the *True Air Speed* for the first or the whole cruising portion of flight, in terms of:
Kilometers per hour, (ICAO only) expressed as “K” followed by 4 figures (e.g., K0830), or
Knots, expressed as “N” followed by 4 figures (e.g., N0485), or

True Mach number, when so prescribed by the appropriate ATS authority, to the nearest hundredth of unit Mach, expressed as “M” followed by 3 figures (e.g., M082).

b. Cruising Level (maximum 5 characters)

INSERT the planned cruising level for the first or the whole portion of the route to be flown, in terms of:

Flight Level, expressed as “F” followed by 3 figures (e.g., F085; F330), or

Standard Metric Level in tens of metres, (ICAO only) expressed as “S” followed by 4 figures (e.g., S1130), when so prescribed by the appropriate ATS authorities, or

Altitude in hundreds of feet, expressed as “A” followed by three figures (e.g., A045; A100), or

Altitude in tens of metres (ICAO only), expressed as “M” followed by four figures (e.g., M0840).

For uncontrolled VFR flights, the letters “VFR” (ICAO only).

c. Route (Including Changes of Speed, Level and/or Flight Rules)**Flights Along Designated ATS Routes**

INSERT if the departure airport is located on, or connected to the ATS route, the designator of the first ATS route (e.g., if departure airport is Ottawa: V300 ULAMO, etc.), or

if the departure airport is not on, or connected to the ATS route:

(ICAO only) the letters DCT, followed by the joining point of the first ATS route, followed by the designator of the ATS route (e.g., if the departure airport is Ottawa: DCT IKLAX T634, etc.);

(Canadian only) by filing the joining point of the first ATS route, followed by the designator of the ATS route (e.g., if departure airport is Ottawa: YOW T616, etc.).

INSERT each point at which either a change of speed or level is planned to commence, or a change of ATS route, or a change of flight rules is planned (e.g., AGLUK/N0200A170 IFR).

CA 3 FLIGHT PLANNING

NOTE: When a transition is planned between a lower and upper ATS route and the routes are oriented in the same direction, the point of transition need not be inserted.

FOLLOWED IN EACH CASE

by the designator of the next ATS route segment, even if the same as the previous one, (e.g., if departure airport is Québec: DICEN T680 LETAK T616, etc.); or

if the flight to the next point is outside a designated route:

(ICAO only) by DCT, unless both points are defined by geographical coordinates (e.g., if the departure airport is Québec: DCT YQB DCT FLEUR DCT YYY, etc.);

(Canadian only) by the next point (e.g., if the departure airport is Québec: YQB FLEUR YYY, etc.). The absence of "DCT" between points on a Canadian flight plan or flight itinerary indicates direct flight.

Flights Outside Designated ATS Routes

ICAO:

INSERT points normally not more than 30 minutes flying time or 370km (200 NM) apart (ICAO only), including each point at which a change of speed or level, a change of track, or a change of flight rules is planned, or when required by appropriate ATS authority(ies),

DEFINE (ICAO only) the track of flights operating predominantly in an east-west direction between 70°N and 70°S by reference to significant points formed by the intersections of half or whole degrees of latitude with meridians spaced at intervals of 10° of longitude. For flights operating in areas outside those latitudes, the tracks shall be defined by significant points formed by the intersection of parallels of latitude with meridians normally spaced at 20° of longitude. The distance between significant points shall, as far as possible, not exceed one hour's flight time. Additional significant points shall be established as deemed necessary.

For flights operating predominantly in a north-south direction, define tracks by reference to significant points formed by the intersection of whole degrees of longitude with specified parallels of latitude which are spaced at 5°.

INSERT DCT between successive points unless both points are defined by geographical coordinates or by bearing and distance.

Canadian:

INSERT points at which a change of speed or level, a change of track, or a change of flight rules is planned. Absence of DCT between points on a Canadian flight plan/itinerary indicates direct flight, or when required by appropriate ATS authority(ies),

Canadian and ICAO:

USE conventions in 1. to 5. and SEPARATE each sub-item by a space.

1. *ATS Route* (2 to 7 characters)

CA 3 FLIGHT PLANNING

The coded designator assigned to the route or route segment including, where appropriate, the coded designator assigned to the standard departure or arrival route (e.g., BCN1, B1, R14, UB10, KODAP2A).

NOTE: Provisions for the application of route designators are contained in ICAO Annex 11, Appendix 1.

2. Significant Point (2 to 11 characters)

The coded designator (2 to 5 characters) assigned to the point (e.g., LN, MAY, HADDY), or

if no coded designator has been assigned, one of the following ways:

- Degrees only (7 characters):

2 figures describing latitude in degrees, followed by “N” (North) or “S” (South), followed by 3 figures describing longitude in degrees, followed by “E” (East) or “W” (West). Make up the correct number of figures, where necessary, by insertion of zeros, e.g., 46N078W.

- Degrees and minutes (11 characters):

4 figures describing latitude in degrees, and tens and units of minutes followed by “N” (North) or “S” (South), followed by 5 figures describing longitude in degrees and tens and units of minutes, followed by “E” (East) or “W” (West). Make up the correct number of figures, where necessary, by insertion of zeros, e.g., 4620N07805W.

- Bearing and distance from a significant point:

The identification of the significant point followed by the bearing from the point in the form of three figures giving degrees magnetic followed by the distance from the point in the form of three figures expressing nautical miles. In areas of high latitude where it is determined by the appropriate authority that reference to degrees magnetic is impractical, degrees true may be used. Make up the correct number of figures, where necessary, by insertion of zeros - e.g., a point 180° magnetic at a distance of 40 NM from VOR “DUB” should be expressed as DUB180040.

3. Change of Speed or Level (maximum 21 characters)

The point at which a change of speed (5% TAS or 0.01 Mach or more) or a change of level is planned, expressed exactly as in 2. above, followed by an oblique stroke and both the cruising speed and the cruising level, expressed exactly as in a. and b. above, without a space between them, even when only one of these quantities will be changed.

EXAMPLES:

LN/N0284A045

MAY/N0305F180

HADDY/N0420F330

4602N07805W/N0500F350

CA 3 FLIGHT PLANNING

46N078W/M082F330

DUB180040/N0350M0840

4. *Change of Flight Rules* (maximum 3 characters)

The point at which the change of flight rules is planned, expressed exactly as in 2. or 3. above, as appropriate, followed by a space and one of the following:

VFR if from IFR to VFR

IFR if from VFR to IFR

EXAMPLES:

LN VFR

LN/N0284A050 IFR

5. *Cruise Climb* (maximum 28 characters)

The letter C followed by an oblique stroke; THEN the point at which cruise climb is planned to start, expressed exactly as in 2. above, followed by an oblique stroke; THEN the speed to be maintained during cruise climb, expressed exactly as in a. above, followed by the two levels defining the layer to be occupied during cruise climb, each level expressed exactly as in b. above, or the level above which cruise climb is planned followed by the letters PLUS, without a space between them.

EXAMPLES:

C/48N050W/M082F290F350

C/48N050W/M082F290PLUS

C/52N050W/M220F580F620

3.15.7 **Item 16: Destination Airport, Total EET, SAR Time (for flights in Canada only) and Destination Alternate Airport(s)**

a. ***Destination Airport and Total EET*** (10 characters max)

ICAO:

INSERT the ICAO four-character location indicator of the destination airport; or

Canadian:

INSERT the four-character location indicator of the destination airport; or

NOTE: In the case of a Canadian flight itinerary, as applicable, the EET may also include the number of days. The total duration of the flight itinerary shall not exceed 30 days,

Canadian and ICAO:

If no location indicator has been assigned,

INSERT ZZZZ and SPECIFY in Item 18 the name of the airport, preceded by DEST/.

CA 3 FLIGHT PLANNING

THEN, without a space, INSERT the total EET.

NOTE: For a flight plan received from an aircraft in flight, the total EET is the estimated time from the first point of the route to which the flight plan applies to the termination point of the flight plan.

INSERT SAR time (4 digits) (maximum of 24 hours)

b. **Destination Alternate Airport(s)**

ICAO:

INSERT the ICAO four-character location indicator(s) of not more than two destination alternate airports, separated by a space, or

Canadian:

INSERT the four-character location indicator of not more than two destination alternate airport, separated by a space; or

Canadian and ICAO:

if no location indicator has been assigned to the alternate airport(s),

INSERT ZZZZ and SPECIFY in Item 18 the name and location of the destination alternate airport(s), preceded by ALTN/.

NOTE 1: No alternate is required on a VFR flight plan or itinerary.

NOTE 2: If departure alternate required insert ZZZZ for second alternate airport and SPECIFY in Item 18 the departure alternate, i.e.: DEP ALTN/ CYOW

3.15.8 Item 18: Other Information

NOTE: Use of indicators not included under this item may result in data being rejected, processed incorrectly, or lost.

Hyphens or oblique strokes should only be used as described below.

S	Satellite data link
H	HF data link
V	VHF data link
M	SSR Mode S data link

INSERT 0 (zero) if no other information, or

Any other necessary information in the sequence shown hereunder, in the form of the appropriate indicator followed by an oblique stroke and the information to be recorded:

STS/	Reason for special handling by ATS, e.g., a SAR mission, as follows:
ALTRV:	for a flight operated in accordance with an altitude reservation;

CA 3
FLIGHT PLANNING

ATFMX:	for a flight approved for exemption from ATFM measures by the appropriate ATS authority;
FFR:	for fire-fighting;
FLTCK:	for a flight check for calibration of NAVAIDS;
HAZMAT:	for a flight carrying hazardous material;
HEAD:	for a flight with Head of State status;
HOSP:	for a medical flight declared by medical authorities;
HUM:	for a flight operating on a humanitarian mission;
MARSA:	for a flight for which a military entity assumes responsibility for separation of military aircraft.
MEDEVAC:	for a life critical medical emergency evacuation;
NONRVSM:	for a non-RVSM capable flight intending to operate in RVSM airspace;
SAR:	for a flight engaged in a search and rescue mission; and
STATE:	for a flight engaged in military, customs or policy services.

Other reasons for special handling by ATS shall be denoted under the designator “RMK/”.

PBN/ Indication of RNAV and/or RNP capabilities: Include as many of the descriptors below as possible that apply to the flight, up to a maximum of eight entries, i.e. not more than 16 characters.

RNAV SPECIFICATIONS	
A1	RNAV 10 (RNP 10)
B1	RNAV 5 all permitted sensors
B2	RNAV 5 GNSS
B3	RNAV 5 DME/DME
B4	RNAV 5 VOR/DME
B5	RNAV 5 INS or IRS
B6	RNAV 5 LORAN C
C1	RNAV 2 all permitted sensors
C2	RNAV 2 GNSS
C3	RNAV 2 DME/DME
C4	RNAV 2 DME/DME/IRU
D1	RNAV 1 all permitted sensors

**CA 3
FLIGHT PLANNING**

RNAV SPECIFICATIONS	
D2	RNAV 1 GNSS
D3	RNAV 1 DME/DME
D4	RNAV 1 DME/DME/IRU

RNP SPECIFICATIONS	
L1	RNP 4
O1	Basic RNP 1 all permitted sensors
O2	Basic RNP 1 GNSS
O3	Basic RNP 1 DME/DME
O4	Basic RNP 1 DME/DME/IRU
S1	RNP APCH
S2	RNP APCH with BARO-VNAV
T1	RNP AR APCH with RF (special authorization required)
T2	RNP AR APCH without RF (special authorization required)

Combinations of alphanumeric characters not indicated above are reserved.

ICAO has not yet allocated a two-digit alphanumeric character to describe RNP 2 under the PBN/ indicator. For an RNP 2 capable flight, enter a Z in item 10 and spell out “RNP2” after NAV/ in item 18: NAV/RNP2.

NAV/ Significant data related to navigation equipment other than specified in PBN/ as required by the appropriate ATS authority. Indicate GNSS augmentation under this indicator, with a space between two or more methods of augmentation, e.g., NAV/GBAS/SBAS.

COM/ Indicate communications applications or capabilities not specified in Item 10(a).

DAT/ Indicate data applications or capabilities not specified in Item 10(a).

SUR/ Include surveillance applications or capabilities not specified in Item 10(b).

DEP/ Name and location of departure airport, if “ZZZZ” is inserted in Item 13, or the ATS unit from which supplementary flight plan data can be obtained, if “AFIL” (airfile) is inserted in Item 13. For airports not listed in the relevant AIP, indicate location as follows:

With four figures describing latitude in degrees and tens and units of minutes, followed by “N” (North) or “S” (South), followed by five figures describing longitude in degrees and tens and units of minutes, followed by “E” (East) or “W” (West). Make up the correct number of figures, where necessary, by insertion of zeros, e.g., 4620N075805W (11 characters); or

Bearing and distance from the nearest significant point, as follows:

CA 3 FLIGHT PLANNING

The identification of the significant point followed by the bearing from the point in the form of three figures giving degrees magnetic, followed by the distance from the point in the form of three figures expressing nautical miles. In areas of high latitude where it is determined by the appropriate authority that reference to degrees magnetic is impractical, degrees true may be used. Make up the correct number of figures, where necessary, by insertion of zeros, e.g., a point of 180° magnetic at a distance of 40 NM from VOR “DUB” should be expressed as DUB180040; or

The first point of the route (name or LAT/LONG) or the marker radio beacon, if the aircraft has not taken off from an airport.

DEST/ Name and location of the destination airport, if “ZZZZ” is inserted in Item 16. For airports not listed in the relevant AIP, indicate location in LAT/LONG or bearing and distance from the nearest significant point, as described under DEP/, above.

DOF/ The date of flight departure in a six-figure format (YYMMDD, where YY equals the year, MM equals the month and DD equals the day).

REG/ The nationality or common mark and registration mark of the aircraft, if different from the aircraft identification in Item 7.

EET/ Significant points or FIR boundary designators and accumulated EETs from takeoff to such points or FIR boundaries, when so prescribed on the basis of regional air navigation agreements, or by the appropriate ATS authority.

EXAMPLES:

EET/CAP0745 XYZ0830/

EET/EINN0204

SEL/ SELCAL Code, for aircraft so equipped.

TYP/ Type(s) of aircraft, preceded if necessary without a space by number(s) of aircraft and separated by one space, if “ZZZZ” is inserted in Item 9.

EXAMPLE: TYP/2F15 5F5 3B2

DLE/ Enroute delay or holding, insert the significant point(s) on the route where a delay is planned to occur, followed by the length of delay using four-figure time in hours and minutes (hhmm).

EXAMPLE: DLE/MDG0030

OPR/ ICAO designator or name of the aircraft operating agency, if different from the aircraft identification in Item 7.

ORGN/ The originator's eight-letter AFTN address or other appropriate contact details, in cases where the originator of the flight plan may not be readily identified, as required by the appropriate ATS authority.

NOTE: In some areas, flight plan reception centers may insert the “ORGN” identifier and originator's AFTN address automatically.

PER/ Aircraft performance data, indicated by a single letter as specified in the *Procedures for Air Navigation Services—Aircraft Operations (PANS-OPS, ICAO Doc 8168), Volume I — Flight Procedures*, if so prescribed by the appropriate ATS authority.

CA 3
FLIGHT PLANNING

ALTN/ Name of destination alternate airport(s), if “ZZZZ” is inserted in Item 16. For airports not listed in the relevant AIP, indicate location in LAT/LONG or bearing and distance from the nearest significant point, as described in DEP/, above.

RALT/ ICAO four-letter indicator(s) for enroute alternate(s), as specified in ICAO Doc 7910—*Location Indicators*, or name(s) of enroute alternate airport(s), if no indicator is allocated. For airports not listed in the relevant AIP, indicate location in LAT/LONG or bearing and distance from the nearest significant point, as described in DEP/, above.

TALT/ ICAO four-letter indicator(s) for takeoff alternate, as specified in ICAO Doc 7910—*Location Indicators*, or name of takeoff alternate airport, if no indicator is allocated. For airports not listed in the relevant AIP, indicate location in LAT/LONG or bearing and distance from the nearest significant point, as described in DEP/, above.

RIF/ The route details to the revised destination airport, followed by the ICAO four-letter location indicator of the airport. The revised route is subject to reclearance in flight.

EXAMPLES:

RIF/DTA HEC KLAX

RIF/ESP G94 CLA YPPH

RMK/ Any other plain-language remarks when required by the appropriate ATS authority or deemed necessary, e.g., TCAS- equipped—ICAO only.

3.15.9 Item 19: Supplementary Information

Endurance:

AFTER E/	INSERT a 4-figure group giving the fuel endurance in hours and minutes.
----------	---

a. *Persons On Board:*

AFTER P/	INSERT the total number of persons (passengers and crew) on board, when required by the appropriate ATS authority. INSERT TBN (to be notified) if the total number of persons is not known at the time of filing.
----------	---

b. *Emergency and Survival Equipment:*

R/ (RADIO)	CROSS OUT indicator U if UHF on frequency 243.0 MHz is not available.
	CROSS OUT indicator V if VHF on frequency 121.5 MHz is not available.
	CROSS OUT indicator E if an Emergency Locator Transmitter (ELT) is not available.

**CA 3
FLIGHT PLANNING**

(Canadian use only) Emergency Locator Transmitter (ELT) categories should be entered in the "ELT TYPE" box on the Flight Plan and Flight Itinerary forms.

S/ (SURVIVAL EQUIPMENT)	CROSS OUT all indicators if survival equipment is not carried. CROSS OUT indicator P if polar survival equipment is not carried. CROSS OUT indicator D if desert survival equipment is not carried. CROSS OUT indicator M if maritime survival equipment is not carried. CROSS OUT indicator J if jungle survival equipment is not carried.
J/ (JACKETS)	CROSS OUT all indicators if life jackets are not carried. CROSS OUT indicator L if life jackets are not equipped with lights. CROSS OUT indicator F if life jackets are not equipped with fluorescein. CROSS OUT indicator U or V or both (as in R/) to indicate radio capability of jackets, if any.
D/ (DINGHIES) (NUMBER)	CROSS OUT indicators D and C if no dinghies are carried, or INSERT number of dinghies carried; and
(CAPACITY)	INSERT total capacity, in persons, of all dinghies carried; and
(COVER)	CROSS OUT indicator C if dinghies are not covered; and
(COLOR)	INSERT color of dinghies if carried.
A/ (AIRCRAFT COLOR AND MARKINGS)	INSERT color of aircraft and significant markings. Tick appropriate box for wheels, skis, etc. (Canadian use only)
N/ (REMARKS)	CROSS OUT indicator N if no remarks, or INDICATE any other survival equipment carried and any other remarks regarding survival equipment. INDICATE if aircraft is equipped with a ballistic parachute system.
ARRIVAL REPORT	(Canadian use only). Fill in the required information.
AIRCRAFT	(Canadian use only). Indicate the aircraft owner, person(s) or company to be notified if search and rescue action is initiated.
C/ (PILOT)	INSERT name of pilot-in-command. INSERT pilot's licence number. (Canadian use only)

Explanation of Figure 3.1 - Composite IFR/VFR/IFR Flight Itinerary

CA 3
FLIGHT PLANNING

- Item 7 Aircraft identification
- Item 8 Y indicates a composite flight of IFR and VFR with the first leg IFR, followed by one or more subsequent changes of flight rules.
F indicates a flight itinerary
G indicates a general aviation aircraft
- Item 9 Aircraft is a Beechcraft 100
- Item 10 S indicates standard COM/NAV equipment of VHF, RTF, VOR, and ILS
D indicates DME equipped
/C indicates transponder Mode A (4 digits-4096 codes) and Mode C
- Item 13 Departure airport is Saskatoon at 0900 UTC
- Item 15 Speed is 170 KIAS.
Altitude is 5000'
Route is V306 to the Lumsden VOR
VFR indicates a change in flight rules to VFR at Lumsden
JQ3 indicates direct flight from Lumsden to the airport at Carlyle (5200) indicates a stopover at Carlyle in hours and minutes
Second JQ3 indicates there will be a stopover at Carlyle
VLN indicates direct flight from Carlyle to the Lumsden VOR
/N0170A060 IFR indicates that the altitude is changed to 6000' and the next leg will be IFR (although the speed did not change, if there is a change to either speed or altitude, both have to be indicated)
Route is V306 from Lumsden to the Saskatoon VOR
- Item 16 Destination airport is Saskatoon
Estimated elapsed time (EET) from takeoff to landing at Saskatoon is 2 days and 6 hours (this includes the flight time and the stopover time at Carlyle.
Search and Rescue (SAR) time of 6 hours indicates the pilot's desire to have SAR action initiated at 6 hours after the total EET of the trip; in other words, 2 days and 12 hours after takeoff from Saskatoon (if there is no entry in this block the SAR activation time would be 24 hours after the EET)
Alternate airport is Prince Albert
- Item 18 Although no other information is provided in this example, this section is for listing any other information as previously described.
- Item 19 Flying time endurance is 5 hours
There are 2 people in the aircraft (including crew)

CA 3
FLIGHT PLANNING

X over U indicates there is no UHF emergency radio

Unaltered V indicates there is VHF emergency radio

Unaltered E under ELT indicates there is an emergency locator transmitter

AP under ELT indicates an automatic portable ELT

Unaltered P under POLAR indicates polar equipment is carried

Unaltered J and L indicates that life jackets with lights are carried

Xs on D and C indicate there are no dinghies

Aircraft color and markings are self explanatory

X on N indicates there are no additional remarks on survival gear

Example indicates closure with Saskatoon tower.

Contact name and number is self explanatory

Pilot's licence number assists SAR specialists in their search

CA 4

AIRPORT OPERATIONS

SECTION 4

4.1 GENERAL

Pilots must be particularly alert when operating in the vicinity of an airport. Increased traffic congestion, aircraft in climb and descent attitudes, and pilots preoccupied with cockpit duties are some of the factors that increase the accident potential near airports. The situation is further compounded when the weather only just meets VFR requirements.

Several operators have, for some time, been using their landing lights when flying at lower altitudes and within terminal areas, both during daylight hours and at night. Pilot comment has confirmed that the use of landing lights greatly increases the probability of the aircraft being seen. An important side benefit for improved safety is that birds appear to see aircraft showing lights in time to take avoiding action. In view of this, it is recommended that, when so equipped, all aircraft use landing lights during the takeoff and landing phases and when flying below 2000 ft AGL within terminal areas and airport traffic patterns.

Air Traffic Control Towers equipped with radar have the capability of providing an increased level of service to the aviation community. The class of airspace determines the controller's responsibilities vis-a-vis separation between IFR and VFR aircraft, and between VFR and VFR aircraft. Control staff in certain towers will be able to assist aircraft in establishing visual separation through the provision of radar vectors, radar monitoring and altitude assignments. Use of the radar will also result in more efficient control of VFR aircraft.

While aircraft shall not be operated at speeds greater than 200 KIAS below 3000 ft AGL and within 10 NM of a controlled airport (CAR 602.32), there is no mandatory speed restriction when operating in the vicinity of an uncontrolled airport. As traffic levels at some of these airports may be high from time to time, the risk of a possible mid-air collision is somewhat elevated during these periods. For this reason, it is recommended that pilots reduce their aircraft speed to the maximum extent possible when operating below 3000 ft AGL and within 10 NM of an uncontrolled airport.

Incidents have occurred, when aircraft are being operated VFR within control zones, when the flight visibility is less than three miles due to a local smoke, haze, rain, snow, fog or other condition. CAR 602.114 requires a minimum of three miles ground visibility for VFR flight within a control zone. This visibility is, of course, taken by a person on the ground and does not preclude the possibility that, due to some restriction, the visibility aloft may be less. Good airmanship requires that a pilot encountering less than three miles flight visibility within a control zone will either:

- a. take action to avoid the area of reduced visibility; or
- b. remain clear of the area of reduced visibility and request a special VFR clearance from ATC.

Pilots shall maintain a listening watch on the appropriate tower frequency while under control of the tower. Whenever possible, requests for radio checks and taxi instructions should be made on the appropriate ground control frequency. After establishing initial contact with the control tower, the pilot will be advised of any frequency changes required.

CA 4 AIRPORT OPERATIONS

4.1.1 Wake Turbulence

Wake turbulence has its greatest impact on departure and arrival procedures; however, pilots should not assume that it will only be encountered in the vicinity of airports. Caution should be exercised whenever a flight is conducted anywhere behind and less than 1000 ft below a large aircraft.

Radar Vectoring

Controllers apply the following wake turbulence radar separation minima between a preceding IFR/VFR aircraft and an aircraft vectored directly behind it and at less than 1000 ft during any phase of flight.

Categories, weight limits, aircraft examples and separation criteria are indicated in the table below.

Category	Limits	Examples	Separation (NM)
SUPER HEAVY (S)	This category currently only applies to Airbus A380 aircraft with a maximum takeoff mass of 560,000kg.	A380-800	Super Heavy behind a Super Heavy – 4 mi.
HEAVY (H)	Aircraft types weighing less than 560,000 kg but more than 136,000kg.	B747/B777/ B767 A340A330/ MD11	Heavy behind a Super Heavy – 6 mi. Heavy behind a Heavy – 4 mi.
MEDIUM (M)	Aircraft types weighing less than 136,000kg but more than 7000 kg.	B757/B737/ A320 ERJ145/ TU154	Medium behind a Super Heavy – 7 mi. Medium behind a Heavy – 5 mi.
LIGHT (L)	Aircraft types weighing 7000kg or less.	C150/C152 C172/C182/ PA38/PA2	Light behind a Super Heavy – 8 mi.
			Light behind a Heavy – 6 mi.
			Light behind a Medium – 4 mi.

Non-Radar Departures

Controllers will apply a two minute separation interval to any aircraft that takes off into the wake of a known heavy aircraft if:

- a. the aircraft concerned commences the takeoff from the threshold of the same runway; or
- b. any following aircraft departs from the threshold of a parallel runway that is located less than 2500 ft away from the runway used by the preceding heavy aircraft.

NOTE: ATC does not apply this two minute spacing interval between a light following a medium aircraft in the above circumstances, but will issue wake turbulence advisories to light aircraft. Con-

CA 4 AIRPORT OPERATIONS

trollers will apply a three minute separation interval to any aircraft that takes off into the wake of a known heavy aircraft, or light aircraft that takes off into the wake of a known medium aircraft if:

- the following aircraft starts its takeoff roll from an intersection or from a point further along the runway than the preceding aircraft; or*
- the controller has reason to believe that the following aircraft will require more runway length for takeoff than the preceding aircraft.*

ATC will also apply separation intervals of up to three minutes when the projected flight paths of any following aircraft will cross that of a preceding heavy aircraft.

In spite of these measures, ATC cannot guarantee that wake turbulence will not be encountered.

Pilot Waivers

ATC tower controllers are required to advise pilots whenever a requested takeoff clearance is denied solely because of wake turbulence requirements. The intention of this advisory is to make pilots aware of the reason for the clearance denial so that they may consider waving the wake turbulence requirement. To aid the pilot's decision, the tower controller will advise the type and position of the wake-creating aircraft. The following phraseologies will be used by the controller in response to a request for takeoff clearance when wake turbulence is a consideration:

Tower: NEGATIVE, HOLD SHORT FOR WAKE TURBULENCE. HEAVY BOEING 747, ROTATING AT 6000 FEET; or

Tower: LINE UP AND WAIT, WAKE TURBULENCE, HEAVY DC10 AIRBORNE AT 2 MILES.

Pilots are reminded that there are some circumstances where wake turbulence separation cannot be waived.

There may be departure situations, such as with a steady cross-wind component, where the full wake turbulence separation minima is not required. The pilot is in the best position to make an assessment of the need for wake turbulence separation. Although controllers are not permitted to initiate waivers to wake turbulence separation minima, they will issue takeoff clearance to pilots who have waived wake turbulence on their own initiative, with the following exceptions:

- a light or medium aircraft taking off behind a heavy aircraft and takeoff is started from an intersection or a point significantly further along the runway, in the direction of takeoff; or*
- a light or medium aircraft departing after a heavy aircraft takes off or makes a low or missed approach in the opposite direction on the same runway; or*
- a light or medium aircraft departing after a heavy aircraft makes a low or missed approach in the same direction on the same runway.*

A pilot-initiated waiver for a VFR departure indicates to the controller that the pilot accepts responsibility for wake turbulence separation. The controller will still issue a wake turbulence cautionary with the takeoff clearance. Controllers are responsible for ensuring wake turbulence minima are met for IFR departures.

CA 4

AIRPORT OPERATIONS

4.1.2 Noise Abatement

Pilots and operators must conform to the applicable provisions of CAR 602.105 — *Noise Operating Criteria*, and CAR 602.106 — *Noise Restricted Runways* (see Section 15: ATC Annex — Canadian Aviation Regulations (CARs)) and applicable noise abatement procedures depicted on Terminal charts.

Noise operating restrictions may be applied at any airport where there is an identified requirement. When applied at an airport, the procedures and restrictions will be set out on airport charts, and shall include procedures and requirements relating to:

- a. preferential runways;
- b. minimum noise routes;
- c. hours when aircraft operations are prohibited or restricted;
- d. arrival procedures;
- e. departure procedures;
- f. duration of flights;
- g. the prohibition or restriction of training flights;
- h. VFR or visual approaches;
- i. simulated approach procedures; and
- j. the minimum altitude for the operation of aircraft in the vicinity of the airport.

Transport Canada recognizes the need for analysis and consultation in the implementation of proposed new or amended noise abatement procedures or restrictions at airports and aerodromes. A process has been developed that includes consultation with all concerned parties before new or amended noise abatement procedures or restrictions can be published in the CAP or the CFS. When the following checklist has been completed for the proposed noise abatement procedures or restrictions, and the resulting analysis has been completed and approved by Transport Canada, the noise abatement procedure or restriction will be published in the appropriate aeronautical publication.

- a. Description of the problem;
- b. Proposed solution (including possible exceptions);
- c. Alternatives (such as alternative procedures or land uses in the community);
- d. Costs (such as revenue impact, direct and indirect costs to the community, airport operator and airport users);
- e. Noise impacts of the proposed solution;
- f. Effects on aircraft emissions;
- g. Effect on current and future airport capacity;
- h. Implications of not proceeding with the proposal;

CA 4

AIRPORT OPERATIONS

- i. Implementation issues (e.g. aircraft technology, availability of replacement aircraft, ground facilities);
- j. Impact on the aviation system;
- k. Safety implications;
- l. Air traffic management;
- m. Fleet impact.

A complete description of the process involved is available on the Internet at: <https://tc.canada.ca/en/aviation/reference-centre/advisory-circulars/advisory-circular-ac-no-302-002>.

4.1.3 Preferential Runway Assignments

At controlled airports, when selecting preferential runways for noise abatement or for other reasons, air traffic controllers consider the runway condition, the effective crosswind component and the effective tailwind component.

The maximum effective crosswind component considered in determining runway selection is 25 kt for arrivals and departures on DRY runways, and 15 kt on WET runways. The maximum effective tailwind component is 5 kt.

During consultation between NAV CANADA, aviation stakeholders and Transport Canada, it was decided that operations on the preferential runway should be allowed to continue when more than 25 percent of the runway is contaminated, provided:

- a. the contamination is only TRACE depth;
- b. the maximum crosswind component does not exceed 15 kt;
- c. the CRFI reported by the airport operator for all segments of the preferential runway is greater than 0.40; and
- d. there are no braking action reports received from pilots that are less than “good.”

If these conditions are not met, the runway most nearly aligned into the wind must be selected.

Although air traffic controllers may select a preferential runway in accordance with the foregoing criteria, pilots are not obligated to accept the runway for taking off or landing. It remains the pilot's responsibility to decide if the assigned runway is operationally acceptable.

4.1.4 Runway Protected Area

Runway protected area procedures aim to ensure the runway protected area will be free of objects, which will provide a safe environment during aircraft operations in the event of a runway excursion, arrival undershoot, or departure overrun by an aircraft.

ATC and FSS will hold vehicles and pedestrians and ATC will hold taxiing aircraft at published holding positions or at least 200 ft from the runway edge until an aircraft taking off or landing has passed the holding traffic.

The airport operator may designate an alternate holding position at a distance from the runway edge that ensures no hazard is created for arriving or departing aircraft. The airport operator may

CA 4

AIRPORT OPERATIONS

also permit pedestrians to operate within the runway protected area when an aircraft is taking off or landing.

Controlled Airports

ATC will not clear an aircraft to take off or land if a holding position is transgressed. If a holding position is transgressed after a takeoff or landing clearance has been issued, ATC will cancel the clearance, unless doing so would create a hazardous situation for the aircraft.

Uncontrolled Airports

FSS will inform pilots of aircraft taking off or landing of runway protected area transgressions and seek the pilots' intentions.

4.2 PRE-DEPARTURE CLEARANCE (PDC)

Pre-departure clearance (PDC) via the airline host is a system that provides instrument flight rules (IFR) departure clearances (DCL) via data link to subscribing airlines at selected airports. The PDC message is sent from the tower to an airline's server. The airline then takes responsibility for delivery of the PDC via either the aircraft communications addressing and reporting system (ACARS) data link or, for non-ACARS-equipped aircraft, through some other means such as a gate printer.

Instead of a verbal readback of the entire clearance, air traffic control (ATC) primarily requires readback of the flight plan unique identifier (FPUI). This is a four-character (three numeric and one alphabetic) code included in the PDC message. See *AIP Canada (ICAO)* GEN 3.4 (not published herein) for a list of airports offering PDC service along with registration instructions.

4.3 DEPARTURE PROCEDURES — CONTROLLED AIRPORTS

The following departure procedures are based on those applicable for an airport that has all available services, and are listed in the order that they would be used. At smaller, less equipped airports some services will be combined; for example, the IFR clearance would be obtained from ground control where there is no separate clearance delivery frequency. Procedures solely applicable to IFR flight are briefly introduced here to establish their sequence. An elaboration thereof may be found in ATC — Instrument Flight Rules — Departure Procedures.

4.3.1 ATIS Broadcasts

If ATIS is available, a pilot should obtain the ATIS information prior to contacting either the ground control or tower. See ATC General para 1.3 for information on ATIS broadcasts.

4.3.2 Clearance Delivery

At locations where a "clearance delivery" frequency is listed, IFR departures should call on this frequency, prior to requesting taxi authorization, normally no more than five minutes prior to engine start. Where a clearance delivery frequency is not listed, the IFR clearance will normally be given after taxi authorization has been received. At several major airports, departing VFR aircraft are required to contact "clearance delivery" before taxiing. These frequencies, where applicable, are found on the Jeppesen IFR Airport Chart for the appropriate airport.

CA 4

AIRPORT OPERATIONS

4.3.3 Radio Checks

If required, radio checks should, wherever possible be requested on frequencies other than ATC frequencies. Normally the establishment of two-way contact with an agency is sufficient to confirm that the radios are functioning properly.

4.3.4 Requests For Push-back or Power-back

Since controllers may not be in a position to see all obstructions which an aircraft may encounter during push-back or power-back, clearance for this maneuver will not be issued by the tower. Pilots are cautioned that it is their responsibility to ensure that push-back or power-back can be accomplished safely prior to initiating aircraft movement.

4.3.5 Taxi Information

Taxi authorization should be requested on the ground control frequency. At locations where a "Clearance Delivery" frequency is listed, pilots should obtain their IFR clearance or a VFR code where applicable on this frequency prior to contacting ground control. Where no "Clearance Delivery" frequency is listed, the IFR clearance will normally be relayed by ground control before or after taxi authorization has been issued. If no flight plan has been filed, the pilot should inform the tower "Clearance Delivery", where available, or ground control of the nature of the flight on initial contact, such as "local VFR" or "proceeding VFR to (destination)".

Pilot: WINNIPEG GROUND, AZTEC GOLF JULIETT VICTOR HOTEL AT HANGAR NUMBER THREE, REQUEST TAXI - IFR EDMONTON EIGHT THOUSAND.

Ground Control: AZTEC GOLF JULIETT VICTOR HOTEL, WINNIPEG GROUND, RUNWAY (number), WIND (in magnetic degrees and knots), ALTIMETER (four-digit group giving the altimeter in inches of mercury), TAXI VIA (runway or other specific point, route), (other information such as traffic, airport conditions), (CRFI, RSC, or RVR when applicable), CLEARANCE ON REQUEST.

Pilot: GOLF JULIETT VICTOR HOTEL.

Under no circumstances may a taxiing aircraft, whether proceeding to or from the active runway, taxi onto an active runway unless specifically authorized to do so.

Upon receipt of a normal taxi authorization, a pilot is expected to proceed to the taxi-holding position for the runway assigned for takeoff. If a pilot is required to cross any runway while taxiing towards the departure runway, the ground or airport controller will issue a specific instruction to cross or hold short. If a specific authorization to cross was not received, pilots should hold short and request authorization to cross the runway. Pilots may be instructed to monitor the tower frequency while taxiing or until a specific point, or they may be advised to "contact tower holding short." The term "*holding short*," when used during the communications transfer, is considered as a location and does not require a readback.

To emphasize the protection of active runways and to enhance the prevention of runway incursions, ATC is required to obtain a readback of runway "hold" instructions. As a good operating practice, taxi authorizations that contain the instructions "hold" or "hold short" should be acknowledged by the pilot providing a readback or repeating the hold point.

CA 4

AIRPORT OPERATIONS

Examples of “hold” instructions that should be read back:

HOLD or HOLD ON (runway number, or taxiway);

HOLD (direction) OF (runway number); or

HOLD SHORT OF (runway number, or taxiway).

Reminder: In order to reduce frequency congestion, readback of ATC taxi instructions, other than those listed above, is not required in accordance with CAR 602.31(1)(a); such instructions are simply acknowledged. With the increased simultaneous use of more than one runway, however, instructions to enter, cross, backtrack or line-up on *any* runway should also, as a good operating practice, be acknowledged by a readback.

EXAMPLE: An aircraft is authorized to backtrack a runway to the holding bay and to report clear when in the holding bay.

Pilot: CHARLIE FOXTROT ALFA BACKTRACKING RUNWAY TWO FIVE AND WILL REPORT IN THE HOLDING BAY.

NOTE: To avoid causing clutter on controllers’ radar displays, pilots should adjust their transponders to “STANDBY” while taxiing and should not switch them to “ON” (or “NORMAL”) until immediately before takeoff.

The tower may instruct aircraft to “line up and wait.” Controllers will issue the name of the runway intersection or taxiway with the authorization if the line-up position is not at the threshold of the departing runway. When more than one entry point for the same runway is in use, ATC will also specify the runway entry point with the instruction to line up at the threshold.

4.3.5.1 *Oblique Angle Intersection Use*

To mitigate the risk of runway incursions, tower controllers will not permit aircraft to use oblique angle intersections (including taxiways or intersecting runways) to access an active runway if the departure threshold and final approach are not visible to the flight crew, except under the following circumstances:

- There are no other routes to access the runway without having to taxi or backtrack onto an active runway; or
- There is a non-routine situation that requires the use of oblique angle intersections because no practical alternative exists. This may include a MEDEVAC flight, a closed taxiway, a disabled aircraft, or disabled vehicles.

4.3.5.2 *Best Practices for Pilots*

A collaborative approach by the aviation industry will help mitigate the risk of collisions from runway incursions.

At uncontrolled airports, pilots are encouraged to avoid using oblique angle intersections that limit their ability to see the active runway threshold and final approach. At controlled airports, pilots are encouraged to avoid requesting to use oblique angle intersections, except when such use can be permitted by tower controllers.

CA 4

AIRPORT OPERATIONS

4.3.6 Taxi Holding Positions

Authorization must be obtained before leaving a taxi holding position, or where holding position marking is not visible or has not been established, before proceeding closer than 200 ft from the edge of the runway in use. At airports where it is not possible to comply with this provision, taxiing aircraft are to remain at a sufficient distance from the runway in use to ensure that a hazard is not created to arriving or departing aircraft.

4.3.7 Taxi Holding Positions During IFR Operations

It is imperative that aircraft do not proceed beyond taxiway holding signs at controlled airports until cleared by ATC. Aircraft proceeding beyond the taxi holding position signs may enter electronically sensitive areas and cause dangerous interference to the glide path or the localizer signals. In Canada, holding position signs and holding position markings normally indicate the boundaries of electronically sensitive areas, and provide safe obstruction clearance distances from landing runways.

When an airport is operating under CAT II/III weather conditions or when its CAT II/III operations plan is in effect, pilots are to observe CAT II or III mandatory holding position signs. When an airport is not operating under CAT II/III weather conditions, or its low visibility operations plan is not in effect, pilots need not abide by the CAT II or III taxiway holding positions and are expected to taxi to the normal taxiway holding position markings, unless advised otherwise by ATC.

At uncontrolled airports, pilots awaiting takeoff should not proceed beyond the holding position signs or holding position markings until there is no risk of collision with aircraft landing, taxiing or departing.

4.3.7.1 *Glide Path Signal Protection Procedures*

The ILS signal will only be protected under the conditions described below.

A controller will protect the glide path signal when:

- The ceiling is less than 1000 ft or visibility is less than three miles, or both; and
- The arriving aircraft is inside the FAF on an ILS approach.

NOTE: At uncontrolled airports, aircraft maneuvering on the ground may enter ILS critical areas during taxi, takeoff or landing.

4.3.8 Takeoff Clearance

When ready for takeoff, the pilot shall request takeoff clearance and should include the runway number. Upon receipt of the takeoff clearance, the pilot shall acknowledge and take off without delay, or inform ATC if unable to do so.

EXAMPLE: *Pilot:* TOWER, JULIETT GOLF TANGO READY FOR TAKEOFF, RUNWAY THREE SIX.

Tower: JULIETT GOLF TANGO, (any special information – hazards, obstructions, turn after take-off, wind information if required, etc.), CLEARED FOR TAKEOFF RUNWAY THREE SIX (or JULIETT GOLF TANGO, FROM GOLF, CLEARED FOR TAKEOFF RUNWAY THREE SIX).

CA 4

AIRPORT OPERATIONS

Pilot: JULIETT GOLF TANGO

Pilots may request to use the full length of the runway for takeoff at any time. If the runway is to be entered at an intersection and back tracking is required, pilots should indicate their intentions and obtain a clearance for the maneuver before entering the runway.

Pilots may request, or the controller may suggest, takeoff using only part of a runway. The pilot's request will be approved, provided noise abatement procedures, traffic and other conditions permit. If suggested by the controller, the available length of the runway will be stated. It is the pilot's responsibility to ensure that the portion of the runway to be used will be adequate for the takeoff run.

To expedite movement of airport traffic and achieve spacing between arriving and departing aircraft, takeoff clearance may include the word "immediate". In such cases, "immediate" is used for the purpose of air traffic separation. On acceptance of the clearance, the aircraft shall taxi onto the runway and take off in one continuous movement. If, in the pilot's opinion, compliance would adversely affect their operations, the pilot should refuse the clearance. Pilots planning a static takeoff (i.e., a full stop after "lined up" on the runway) or a delay in takeoff, should indicate this when requesting takeoff clearance. ATC will specify the name of the taxiway or intersection with the clearance for takeoff from a taxiway or runway intersection. When more than one entry point for the same runway is in use, ATC will also specify the threshold as the point from which the take-off run will commence for those aircraft departing from the threshold. A controller may not issue a clearance that would result in a deviation from established noise abatement procedures or wake turbulence separation minima.

4.3.8.1 *Air Traffic Control (ATC) Phraseology When a Runway Is Temporarily Shortened Due to Construction*

Whenever the length of a runway has been temporarily shortened due to construction, tower controllers will use the word "shortened" immediately following the runway number for all line-up and take-off clearances.

NOTE: These changes do not transfer pilot responsibility to the controller, but they do ensure that changes in runway length due to construction are communicated as an additional layer of safety.

EXAMPLE: Tower Line up Clearance: GOLF JULIET ECHO TANGO LINE UP RUNWAY ONE - SIX SHORTENED.

4.3.8.2 *Clearance for Aborting a Takeoff*

Aborting a takeoff is an emergency procedure used by a pilot when continuing the takeoff would present a grave hazard to the aircraft. A controller-initiated aborted takeoff is an extreme measure used only where no clear alternative exists.

EXAMPLE: Tower: ALPHA BRAVO CHARLIE, ABORT ABORT. ALPHA BRAVO CHARLIE, ABORT ABORT (reason).

4.3.9 *Release From Tower Frequency*

Unless otherwise advised by ATC, pilots do not require permission to change from tower frequency once clear of the control zone and *should not* request release from this frequency or

CA 4

AIRPORT OPERATIONS

report clear of the zone when there is considerable frequency congestion. When practicable, it is recommended that a pilot of a departing aircraft monitor tower frequency until 10 NM from the control zone.

VFR flights will not normally be released from tower frequency while operating within the control zone. Once outside control zones, or when departing from an uncontrolled airport where a mandatory frequency (MF) has been assigned, beyond the range within which MF procedures apply, pilots should monitor frequency 126.7 MHz.

4.3.10 Departure Procedures — NORDO Aircraft

Before proceeding to any portion of the maneuvering area of a controlled airport, it is the pilot's responsibility to inform the control tower of his/her intentions and make appropriate arrangements for visual signals.

NOTE: Before operating within a control zone with Class C airspace, a clearance shall be obtained from the control tower.

A pilot should remain continuously alert for visual signals from the control tower.

An aircraft should remain at least 200 ft from the edge of any runway where holding position markings or signs are not visible or have not been established unless a clearance for takeoff or to cross the runway has been received.

When stopped by a red light, a pilot must wait for a further clearance before proceeding.

When ready for takeoff by day, the pilot may attract the attention of the airport controller by turning the aircraft toward the tower.

Acknowledgement of Visual Signals — A pilot shall, where practical, acknowledge all clearances and instructions received by visual signals by day, by full movement of rudder or ailerons, whichever can be seen most easily (such movement should be repeated at least three times in succession), or by taxiing the aircraft to the authorized position.

4.3.11 Visual Signals

Visual signals used by the tower and their meanings are as follows:

TO AIRCRAFT ON THE GROUND:		
1	SERIES OF GREEN FLASHES	Cleared to taxi.
2	STEADY GREEN LIGHT	Cleared for takeoff.
3	SERIES OF RED FLASHES	Taxi clear of landing area in use.
4	STEADY RED LIGHT	Stop.
5	FLASHING WHITE LIGHT	Return to starting point on the airport.
6	BLINKING RUNWAY LIGHTS	Advises vehicles and pedestrians to vacate runways immediately.

CA 4 AIRPORT OPERATIONS

4.3.12 Departure Procedures — ONLY Aircraft

The procedures which apply to aircraft without radio also apply to aircraft equipped with receiver only, except that an airport controller may request the pilot to acknowledge a transmission in a specific manner. After the initial acknowledgement no further acknowledgement, other than compliance with clearances and instructions, is necessary, unless otherwise requested by the controller.

4.4 TRAFFIC CIRCUITS — CONTROLLED AIRPORTS

The following procedures apply to all airports at which a control tower is in operation.

The traffic circuit consists of the crosswind leg, downwind leg, base leg, and final approach leg.

Figure 4.1 — Standard Left-Hand Traffic Circuit

NOTE:

- a. Circuit normally flown at 1000 ft AAE.
- b. Where a right-hand circuit is required in accordance with CAR 602.96, the opposite of this diagram is applicable.

Entry to the circuit shall be made in such a manner so as to avoid “cutting off” other aircraft, conforming as closely as possible to the altitude (normally 1000 ft AAE), speed and size of the circuit being flown by other traffic.

In order to increase safety by reducing the possibility of conflicting with departing traffic, aircraft approaching the active runway from the upwind side are to join the downwind leg abeam a point approximately midway between each end of the runway, taking into account aircraft performance, wind and/or runway length.

CA 4

AIRPORT OPERATIONS

Pilots of NORDO and RONLY aircraft, who have made specific arrangements to operate within the control zone (paras 4.5.5 and 4.5.6), should approach the circuit from the upwind side, join crosswind at circuit height and, taking due account of other traffic, join the circuit on the downwind leg. Pilots are cautioned to remain clear of the approach and/or departure path of the active runway when joining the circuit (see Figure 4.1). Flights which are not in communication with the tower shall, at all times, be on the alert for visual signals. Pilots are reminded that below 3000 ft AGL and within 10 NM of a controlled airport, aircraft shall not be operated at speeds greater than 200 KIAS. However, where the minimum speed of the aircraft is greater than 200 KIAS, the aircraft may be operated at the minimum safe speed. (CAR 602.32).

4.5 ARRIVAL PROCEDURES — CONTROLLED AIRPORTS

If ATIS is available, all arrivals should monitor this frequency to obtain the basic airport information prior to contacting the tower. (See ATC General para 1.3 for ATIS information.)

4.5.1 Initial Contact

Pilots must establish and maintain radio communications with the appropriate control tower prior to operating within any control zone served by an operational control tower. Also, if the control zone is Class B or C airspace, the appropriate clearance must be received from the controlling agency prior to entry.

When practical, it is recommended that the pilot make initial contact at least 5 minutes prior to requiring clearance or entering the zone.

4.5.2 Initial Clearance

On initial contact with the tower, unless the pilot advises receipt of ATIS, the airport controller will inform the pilot of runway in use, wind direction and speed, altimeter setting and any other pertinent information. Following this, the pilot will receive clearance to proceed, including any necessary restrictions. The shortest routing to the runway may be expected if traffic permits. Pilots of VFR aircraft should check the Canadian Airport Directory (or a VTA chart if applicable) for special procedures at the time of flight planning.

When a pilot is given a clearance “to the circuit” by ATC, it is expected that the aircraft will join the circuit on the downwind leg at circuit height. Depending on the direction of approach to the airport and the runway in use, it may be necessary to proceed crosswind prior to joining the circuit on the downwind leg.

The ATC phraseology “cleared to the circuit” authorizes a pilot to make a right turn in order to join crosswind, or partial right turn to join a left-hand circuit provided that the right turn or partial right turn can be carried out in safety.

A straight-in approach is an approach where an aircraft joins the traffic circuit on the final leg without having executed any other portion of the circuit.

When an aircraft is cleared for a right-hand approach while a left-hand circuit is in effect, it shall be flown so as to join the circuit on the right-hand downwind leg, or join directly into the right hand base leg, as cleared by the airport controller.

CA 4 AIRPORT OPERATIONS

Pilot: KELOWNA TOWER, CESSNA FOXTROT ALFA BRAVO CHARLIE, ONE FIVE MILES NORTH, SIX THOUSAND FIVE HUNDRED FEET VFR, REQUEST LANDING INSTRUCTIONS.

Tower: CESSNA FOXTROT ALFA BRAVO CHARLIE, KELOWNA TOWER, RUNWAY (number), WIND (direction in degrees magnetic, speed in knots), ALTIMETER (4-digit group in inches), (other pertinent instructions or information if deemed necessary), CLEARED TO THE CIRCUIT or CLEARED TO LEFT BASE LEG or CLEARED STRAIGHT-IN APPROACH.

Pilot: ALFA BRAVO CHARLIE.

When a pilot has received current landing information from the tower or the ATIS broadcast, initial clearance may be requested as follows:

Pilot: VICTORIA TOWER, CESSNA FOXTROT ALFA BRAVO CHARLIE (aircraft position), ALTITUDE, CHECK LANDING INFORMATION (or) WITH INFORMATION (ATIS code). REQUEST CLEARANCE TO THE CIRCUIT (or other type of approach).

Once established in the circuit as cleared, the pilot is to advise the tower accordingly.

Pilot: TOWER, ALFA BRAVO CHARLIE DOWNWIND.

Tower: ALFA BRAVO CHARLIE NUMBER (approach sequence number). If not Number 1, the tower will give the type, position and color if significant, of aircraft to follow and other instructions or information.

Pilot: ALFA BRAVO CHARLIE.

Common ATC Phraseologies:

FOLLOW (aircraft type) NOW ON BASE LEG.

EXTEND DOWNWIND.

WIDEN APPROACH.

VFR Holding Procedures

When it is required by traffic, VFR flights may be asked to ORBIT visually over a geographic location, VFR checkpoint (when these are published in the CFS or VTA charts) (not published herein) until they can be cleared to the airport. If the request is not acceptable, pilots should inform ATC and state their intentions.

Pilot: TORONTO TOWER, CESSNA FOXTROT ALFA BRAVO CHARLIE, OVER PORT CREDIT AT THREE THOUSAND FIVE HUNDRED FEET WITH INFORMATION ROMEO.

Tower: CESSNA FOXTROT ALFA BRAVO CHARLIE, TORONTO TOWER, ORBIT THE FOUR STACKS, ANTICIPATE A FIVE MINUTE DELAY, TRAFFIC IS A CESSNA ONE SEVEN TWO OVER THE FOUR STACKS, LAST REPORTED AT TWO THOUSAND FEET.

The pilot is expected to proceed to the FOUR STACKS, orbit within visual contact of the checkpoint and be prepared to proceed to the airport immediately upon receipt of a further clearance. Left turns are recommended as terrain and collision avoidance are the pilot's responsibility.

Tower: ALFA BRAVO CHARLIE, REPORT LEFT BASE FOR RUNWAY TWO FOUR LEFT. CLEARED TO THE CIRCUIT.

CA 4

AIRPORT OPERATIONS

Pilot: ALFA BRAVO CHARLIE DEPARTING THE FOUR STACKS AT THIS TIME, WILL REPORT LEFT BASE TO RUNWAY TWO FOUR LEFT; or

Pilot: ALFA BRAVO CHARLIE

4.5.3 Landing Clearance

At controlled airports, a pilot must obtain landing clearance prior to landing. Normally the airport controller will initiate landing clearance without having first received the request from the aircraft; however, should this not occur, the onus remains upon the pilot to request such clearance in sufficient time to accommodate the operating characteristics of the aircraft being flown. NORDO and RONLY aircraft should be considered as intending to land when they join and conform to the traffic circuit. Landing clearance will normally be given when an aircraft is on final approach. If landing clearance is not received, the pilot should, except in case of emergency, pull up and make another circuit.

Pilot: TOWER, ALFA BRAVO CHARLIE LANDING CLEARANCE RUNWAY TWO SIX.

Tower: ALFA BRAVO CHARLIE, CLEARED TO LAND RUNWAY TWO SIX.

Pilot: ALFA BRAVO CHARLIE.

Controllers may, on occasion, authorize ground traffic to cross the landing runway after a landing clearance has been issued. Any such authorization by ATC is given with the assurance that the runway will be clear of conflicting traffic at the time the arriving aircraft crosses the landing threshold. When it appears that the runway may not be clear for landing, the pilot will be advised to "CONTINUE APPROACH, POSSIBLE PULL-UP". When a "pull-up" is necessary (before or after landing clearance has been issued), the pilot shall abandon the approach and make another circuit.

Tower: ALFA BRAVO CHARLIE, TRAFFIC STILL ON RUNWAY, PULL-UP AND GO AROUND.

Common ATC Phraseologies:

CAUTION, POSSIBLE TURBULENCE FROM LANDING (aircraft type and position).

MAKE LEFT/RIGHT THREE SIX ZERO.

MAKE FULL-STOP LANDING.

CONTACT TOWER/GROUND ON (frequency) WHEN OFF RUNWAY/NOW.

The "Cleared for the Option" procedure has been introduced to give a pilot the option to make a touch-and-go, low approach, missed approach, stop-and-go, or a full stop landing. This procedure will normally be used during light traffic conditions.

Pilot: TOWER, ALFA BRAVO CHARLIE, DOWNWIND RUNWAY TWO SEVEN, REQUEST THE OPTION.

Tower: ALFA BRAVO CHARLIE, CLEARED FOR THE OPTION RUNWAY TWO SEVEN.

A clearance for a multiple touch-and-go permits the pilot to perform more than one touch-and-go during a single pass along the runway without stopping. The procedure is intended for student pilots training with an instructor and will only be authorized during light traffic conditions.

CA 4

AIRPORT OPERATIONS

Pilot: TOWER, ALFA BRAVO CHARLIE, DOWNWIND RUNWAY TWO SEVEN, REQUEST MULTIPLE TOUCH-AND-GO.

Tower: ALFA BRAVO CHARLIE, CLEARED MULTIPLE TOUCH-AND-GO, RUNWAY TWO SEVEN.

4.5.3.1 ***Air Traffic Control (ATC) Phraseology When a Runway Is Temporarily Shortened Due to Construction***

Whenever the length of a runway has been temporarily shortened due to construction, tower controllers will use the word “shortened” immediately after the runway number on initial contact with arrivals and for all landing clearances.

NOTE 1: These changes do not transfer pilot responsibility to the controller, but they do ensure that changes in runway length due to construction are communicated as an additional layer of safety.

NOTE 2: For repetitive operations (ex. circuits), ATC will use the term “shortened” only for the first arrival/departure clearance.

EXAMPLE: Tower landing clearance: GOLF JULIET ECHO TANGO CLEARED TO LAND RUNWAY ONE-SIX SHORTENED.

4.5.4 **Taxiing**

A pilot must obtain an ATC authorization to taxi on the maneuvering area at a controlled airport. Unless otherwise instructed by the airport controller, aircraft are expected to continue in the landing direction to the nearest suitable taxiway, exit the runway without delay and obtain further authorization to taxi. No aircraft shall exit a runway onto another runway unless instructed or authorized to do so by ATC. When required, ATC will provide the pilot with instructions for leaving the runway. These instructions will normally be given to the pilot prior to landing or during the landing roll. When an aircraft is instructed to exit onto another runway, the pilot must:

- a. obtain further authorization to taxi; and
- b. remain on tower frequency until clear of that runway or until communication is transferred to ground control.

After landing on a dead-end runway, the pilot will normally be given instructions to backtrack. In all cases, after leaving the runway, unless otherwise instructed by ATC, pilots should continue to taxi forward across the taxi holding position lines or to a point at least 200 ft from the edge of the runway where a taxi holding position line is not available. The aircraft is not considered clear of the runway until all parts of the aircraft are past the taxi holding position line or the 200-ft point. When clearing landing runways onto taxiways or other runways, pilots should exercise good airmanship by continuing to taxi well clear of the hold position while contacting ground control to obtain taxi clearance. This is to prevent aircraft from blocking a runway exit to following aircraft. If unable to establish contact with ground control, pilots should stop and not cross any runway without receiving ATC authorization.

Tower: ALFA BRAVO CHARLIE (instructions for leaving runway), CONTACT GROUND (specific frequency).

CA 4

AIRPORT OPERATIONS

Towers will normally provide the aircraft down time only when requested by the pilot.

Normally, aircraft will not be changed to ground control until off the active runway or runways.

Tower: ALFA BRAVO CHARLIE, TAXI TO (apron or parking area) (any special instructions such as routing, traffic, cautionary or warning regarding construction or repair on the maneuvering areas).

4.5.5 Arrival Procedures — NORDO Aircraft

Before operating into a controlled airport, pilots shall contact the control tower, inform the tower of their intentions and make arrangements for clearance through visual signals.

NOTE: Before operating within a control zone with Class C airspace, a clearance shall be obtained from the control tower.

Pilots should remain continuously alert for visual signals from the control tower.

Traffic Circuit — The pilot should approach the traffic circuit from the upwind side of the runway, join crosswind at circuit height abeam a point approximately midway between each end of the runway and join the circuit on the downwind leg. While within the circuit the pilot should conform to the speed and size of the circuit, maintaining such separation from aircraft ahead that a landing can be made without overtaking it. If it is necessary for a flight to cross the airport prior to joining crosswind, this should be done at least 500 ft above circuit height, and descent to circuit height should be made in the upwind area of the active runway.

Final Approach — Before turning on final approach, a pilot shall check for any aircraft on a straight-in approach.

Landing Clearance — Landing clearance will be given on final approach. If landing clearance is not received, the pilot shall, except in case of emergency, pull up and make another circuit. (Landing clearance may be withheld by the tower when there are preceding aircraft which have not landed or if the runway is occupied).

Taxiing — No taxi clearance is required after landing, except to cross any runway or to taxi back to a turn-off point. When an aircraft's landing run carries it past the last available turn-off point, it should proceed to the end of the runway and taxi to one side, waiting there until an instruction is received to taxi back to the nearest turn-off point.

4.5.6 Arrival Procedures — RONLY Aircraft

The procedures which apply to aircraft without radio also apply to aircraft equipped with receiver only, except that an airport controller may request the pilot to acknowledge a transmission in a specified manner. After the initial acknowledgement, no further acknowledgement other than compliance with clearances and instructions is necessary, unless otherwise requested by the controller.

4.5.7 Visual Signals

Visual signals used by the tower and their meanings are as follows:

CA 4
AIRPORT OPERATIONS

TO AIRCRAFT IN FLIGHT:

1	STEADY GREEN LIGHT	Cleared to land.
2	STEADY RED LIGHT	Give way to other aircraft and continue circling.
3	SERIES OF GREEN FLASHES	Return for landing. (This shall be followed at the proper time by a steady green light.)
4	SERIES OF RED FLASHES	Airport unsafe; do not land.
5	FIRING OF A RED PYROTECHNICAL LIGHT (SEE NOTE)	Whether by day or night and notwithstanding previous instructions, means do not land for the time being.
<i>NOTE: Military control towers only.</i>		

Acknowledgement of Visual Signals — A pilot shall, where practicable, acknowledge all clearances and instructions received by visual signals. Signals may be acknowledged as follows:

- a. distinct rocking of aircraft in flight;
- b. at night, by a single flash of a landing light.

4.5.8 Communications Failure — VFR

- a. CAR 602.138 specifies that where there is a two-way radio communication failure between the controlling air traffic control unit and a VFR aircraft while operating in Class B, Class C or Class D airspace, the pilot-in-command shall:
 1. leave the airspace
 - (a) where the airspace is a control zone, by landing at the airport for which the control zone is established, and
 - (b) in any other case, by the shortest route;
 2. where the aircraft is equipped with a transponder, set the transponder to code 7600; and
 3. inform an air traffic control unit as soon as possible of the actions taken pursuant to (1).
- b. Should the communications failure occur while operating outside of Class B, C, or D airspace precluding the pilot from obtaining the appropriate clearance to enter or establishing radio contact, and if no nearby suitable airport is available, the pilot may enter the Class B, C or D airspace, continue under VFR, and shall carry out the remaining procedures listed in **a.**

Should the communications failure occur and there is a suitable airport nearby at which the pilot wishes to land, it is recommended that the pilot comply with the established NORDO arrival procedure outlined in para 4.5.5.

Pilots operating VFR in either Class E or G airspace may follow the procedures in **a.** even though there is no intention to enter Class B, C, or D airspace.

CA 4
AIRPORT OPERATIONS

4.5.9 Operations on Intersecting Runways

ATC procedures allow for sequential and/or simultaneous operations on intersecting runways.

Their intent is to increase airport traffic capacity, thus reducing delays and saving fuel. These operations differ only in the controllers' application of ATC procedures; ATC advisories will specify the type of operation(s) in progress.

a. Sequential Operations

Sequential operations do not permit controllers to allow either an arriving aircraft to cross the arrival threshold or a departing aircraft to commence its takeoff roll until certain conditions are met.

For an arriving aircraft (Figure 4.2) the conditions are as follows:

1. the preceding departing aircraft has:
 - (a) passed the intersection, or
 - (b) is airborne and has turned to avoid any conflict;
2. the preceding arriving aircraft has:
 - (a) passed the intersection, or
 - (b) completed its landing roll and will hold short of the intersection (i.e. stopped or at taxi speed), or
 - (c) completed its landing roll and turned off the runway.

Figure 4.2 — Arriving Aircraft

For a departing aircraft (Figure 4.3) the sequential conditions are listed below:

3. the preceding departing aircraft has:
 - (a) passed the intersection; or
 - (b) is airborne and has turned to avoid any conflict;

CA 4 AIRPORT OPERATIONS

4. the preceding arriving aircraft has:

- (a) passed the intersection; or
- (b) completed its landing roll and will hold short of the intersection (i.e. stopped or at taxi speed); or
- (c) completed its landing roll and turned off the runway.

Figure 4.3 — Departing Aircraft

b. *Simultaneous Operations*

Simultaneous operations differ from sequential operations in the application of ATC procedures. The procedures for simultaneous use of intersecting runways are applied only between two arrivals or an arrival and a departure. Air Traffic Controllers will permit an arriving aircraft to cross the runway threshold or a departing aircraft to begin its takeoff roll provided one of the aircraft has accepted a clearance to land and “hold short” of the intersecting runways (Figure 4.4). These operations are known as Land and Hold Short Operations (LAHSO).

General

LAHSO may be carried out under the following conditions:

1. the landing distance available (LDA), measured from the threshold, or displaced threshold, to 200 ft short of the nearest edge of the runway being intersected, must be published. ATC shall also broadcast LAHSO advisories, including LDAs, through an ATIS or voice advisory, well in advance of the final approach descent;
2. the weather minima of a 1000 ft ceiling and visibility of three statute miles are required. In specific cases, these criteria may be reduced by the Regional Director, Civil Aviation, but only with a written agreement between ATC and the operator;
3. the reported braking action must not be less than *good*. The runway must be bare. (No snow, slush, ice, frost, or standing water is visible from the tower or reported by a competent person. In order to accommodate small accumulations of ice or snow at the runway edge during winter operations, only the center 100 ft of the runway must be bare.);

CA 4 AIRPORT OPERATIONS

4. a tailwind of less than five knots is acceptable for normal LAHSO on both dry and wet runway operations. The maximum allowable crosswind component for dry runways is 25 kt and 15 kt for LAHSO. Controllers will not initiate or approve a request for LAHSO on any runway when crosswinds on that runway exceed the maximum;
5. ATC must include specific directions to hold short of an intersecting runway (e.g., "cleared to land Runway 27, hold short of Runway 36"). Pilots, in accepting the clearance, must read back "cleared to land Runway 27, hold short of Runway 36". Having accepted the "hold short" clearance, *pilots are obligated to remain 200 ft short of the closest edge of the runway being intersected*. If, for any reason, a pilot is unsure of being able to comply with a "hold short" clearance, the pilot must advise ATC immediately of non-acceptance of the clearance; *it is far better to be safe than sorry*;
6. the lines are the same as Taxiway Exit and Holding Markings. These lines shall be located on the runway 90 degrees to the "hold short" runway center line, 200 ft short of the nearest edge of the runway being intersected. Red and white mandatory instruction signs, illuminated for night LAHSO, shall be located at either end of the lines. More details on lines can be found in *Aerodrome Standards and Recommended Practices* (TP 312E); and
7. for tactical ATC reasons, controllers may offer or approve a pilot request for the use of a dry runway for landing with a tailwind not exceeding ten knots. LAHSO will not be authorized on wet runways if the tailwinds are five knots or more.

NOTE: LAHSO is not authorized if thunderstorms, turbulence, wind shear or other conditions exist that would adversely affect the restricted aircraft's ability to "hold short" after landing.

Figure 4.4 — Aircraft with Hold Short Clearance

For simultaneous operations involving helicopters (Figure 4.5), if the arriving helicopter has a "hold short" clearance, its point of landing is at least 700 ft from the center line of the other runway.

CA 4
AIRPORT OPERATIONS

Figure 4.5 — Helicopter with Hold Short Clearance

Wet Runways

The following conditions are applicable for wet runway operations:

1. no Group 6 aircraft shall be instructed to hold short of an intersecting runway;
2. stopping distances for Group 1, 2 and 3 aircraft are increased by 15% (see Note), and
3. the coefficient of friction on LAHSO runways must meet a minimum standard. The coefficient of friction will be measured in accordance with *Airport Pavement Evaluation—Surface Friction* (AK-68-35-000/TP3716); only those runways with average coefficients of friction above 0.6 will be approved for wet runway LAHSO.

NOTE: Aircraft are categorized into groups requiring the following stopping distances:

	Dry Runway	Wet Runway
Group 1	1650 feet	1900 feet
Group 2	3000 feet	3500 feet
Group 3	4500 feet	5200 feet
Group 4	6000 feet	6000 feet
Group 5	8000 feet	8000 feet
Group 6	8400 feet	8400 feet

These stopping distances are based on ISA conditions for sea level runways. For higher airport elevations the distances are adjusted for pressure altitude. An aircraft's grouping is such that its normal stopping distance is approximately 50% of the available stopping distance.

c. General Provisions

1. All pilots will be advised that simultaneous LAHSO are in progress.
2. Controllers will issue appropriate traffic information.

CA 4

AIRPORT OPERATIONS

3. Acceptance of a “hold short” landing clearance indicates to the controller that a pilot is able to comply with the clearance. If for any reason a pilot elects to use the full length of a runway, or a different runway, the pilot should inform ATC on or before receipt of the “hold short” landing clearance.

NOTE: During sequential and/or simultaneous operations, ATC Procedures and pilot compliance with clearance conditions will ensure aircraft separation (i.e. spacing between aircraft). Notwithstanding this, conflicts between aircraft may occur, particularly at runway intersections, if a pilot does not comply with a clearance or is unable to comply due to unforeseen circumstances such as missed approaches, misjudged landings, balked landings or brake failures. In these circumstances, ATC will endeavour to provide traffic advisories and/or instructions to assist pilots with collision avoidance.

4.5.10 High Intensity Runway Operations (HIRO)

Several of Canada's airports rank among North America's busiest in total air carrier movements. HIRO, as a concept, has evolved from procedures developed by high density terminals in North America and Europe. It is intended to increase operational efficiency and maximize the capacity at those airports where it is employed through the use of disciplined procedures applied by both pilots and air traffic controllers. HIRO is intended to minimize the occurrence of overshoots that result from slow-rolling and/or slow-clearing aircraft and offers the prospective of reducing delays overall, both on the ground and in the air. In its fullest application, HIRO enables ATC to apply minimum spacing to aircraft on final approach to achieve maximum runway utilization.

The tactical objective of HIRO is to minimize runway occupancy times (ROT) for both arriving and departing aircraft, consistent with both safety and passenger comfort. Effective participation in HIRO results when the pilot of an arriving aircraft exits the runway expeditiously, allowing the following arriving aircraft to cross the threshold with a minimum time interval. In the case of an arrival and a subsequent departure, the arriving pilot clears the runway in a minimum ROT, permitting a departure before the next arrival crosses the threshold. The air traffic controller's objective in HIRO is to optimize approach spacing. This can be best achieved when pilots reach and adhere to assigned speeds as soon as practicable.

Effective participation In HIRO is achieved by satisfying the following key elements.

Key elements for arrivals:

- The pilot's objective should be to achieve minimum ROT, within the normally accepted landing and braking performance of the aircraft, by targeting the earliest *suitable* exit point and applying the right deceleration rate so that the aircraft leaves the runway as expeditiously as possible at the nominated exit.
- The expected runway exit point to achieve minimum ROT should be nominated during approach briefing. It is better, in terms of ROT, to select an exit you know you can make, rather than choose an earlier one, miss it, and then roll slowly to the next available exit.
- Upon landing, pilots should exit the runway without delay.

High-speed exits have specific maximum design speeds. These speeds may be available through the appropriate airport authority. Key elements for departures:

CA 4

AIRPORT OPERATIONS

- On receipt of a line-up clearance, pilots should ensure that they are able to taxi to position and line up on the runway as soon as the preceding aircraft has commenced its take-off roll.
- ATC will expect aircraft to enter the runway at a suitable angle to quickly line up on the center-line and, when possible, continue in to a rolling takeoff when cleared. Pilots should ensure that they are able to commence the take-off roll immediately when a take-off clearance is issued.
- Aircraft that need to enter the runway at right angles, to backtrack, or to use the full length of the runway will require extra time on the runway. Therefore, pilots should notify ATC before arriving at the holding area so that the controller can re-sequence departures to provide the extra time.
- Cockpit checks should be completed prior to line-up and any checks requiring completion on the runway should be kept to a minimum. If extra time is required on the runway, ATC should be informed before the aircraft arrives at the holding area so that the controller can re-sequence departures to provide the extra time.

4.6 AIRCRAFT OPERATIONS — UNCONTROLLED AIRPORTS

4.6.1 General

An uncontrolled airport is an airport without a control tower, or one where the tower is not in operation. There is no substitute for alertness while in the vicinity of an uncontrolled airport. It is essential that pilots be aware of and look for other traffic, and exchange traffic information when approaching or departing from an uncontrolled airport, particularly since some aircraft may not have communication capability. To achieve the greatest degree of safety, it is essential that all radio-equipped aircraft monitor a common designated frequency, such as the published MF or ATF, and follow the reporting procedures specified for use in an MF area, while operating on the maneuvering area or flying within an MF area surrounding an uncontrolled airport.

“MF area” means an area in the vicinity of an uncontrolled airport for which an MF has been designated. Normally, the MF area is a circle with a 5 NM radius capped at 3,000 feet AAE.

At uncontrolled airports without a published MF or ATF, the common frequency for the broadcast of aircraft position and pilot’s intentions flying in the vicinity of that airport is 123.2 MHz.

At airports within an MF area, traffic information may be exchanged by communicating with an FSS, CARS, UNICOM operator, vehicle operator, or by a broadcast transmission. The VCS in conjunction with Airport Advisory Service (AAS) is normally provided at airports served by an FSS. Some uncontrolled airports are indirectly served by an FSS through an RCO and may provide RAAS. As Flight Service Specialists may be located some distance from an airport, it is essential that they be kept fully informed of both aircraft and vehicle activity.

Other airports are designated as having an ATF. At some airports with a control tower or FSS, an ATF is designated for use when the air traffic facility is closed. If a radio-equipped vehicle is present at ATF airports, pilots can contact the vehicle operator directly on the ATF to ascertain that no vehicle-aircraft conflict exists. Operators of such radio-equipped vehicles will also provide pilots with any other available information on runway status and presence of other aircraft or vehicles on the runway.

CA 4

AIRPORT OPERATIONS

There are some remote airports where a Voice Generator Module (VGM) connected to an AWOS (or LWIS) continuously broadcasts weather information. An AWOS (or LWIS) broadcasts weather information that may differ from the METAR or SPECI issued for the location. There may also be significant differences between broadcasts only a few minutes apart. Transport Canada recognizes that for any given site at any given time there can be only one official weather observation (METAR or SPECI), whether from a human observer or an automated station. As a result, it has been determined that although an AWOS (or LWIS) broadcast constitutes an additional source of accurate, up-to-the-minute weather information, it does not constitute an official weather observation (METAR or SPECI).

The wind and altimeter data obtained from an AWOS (or LWIS) via a VGM broadcast can be used to conduct an instrument approach. Therefore, at airports where a Remote Aerodrome Advisory Service (RAAS) is provided and where AWOS (or LWIS) weather information is also available via a VGM broadcast, the wind and altimeter data may be omitted from the RAAS if the pilot indicates in the initial call to the FSS that the weather information has already been obtained from the VGM broadcast. To avoid unnecessary frequency changes and to assist in reducing frequency congestion, it is desirable that pilots acquire this weather information prior to entering either a MF or ATF area and inform the flight service specialist that they have the wind and altimeter information. On start-up at such an airport, it would be desirable to listen to the VGM broadcast prior to taxiing.

The flight service specialist will advise pilots of below minima conditions reported in the current official METAR or SPECI. This will ensure a common reference for pilots and ATS personnel since IFR or SVFR authorization would then be required to operate within the control zone. Pilots will also be advised of any other significant weather conditions reported in current METAR, SPECI, SIGMET, AIRMET or PIREP, as appropriate, that may affect the safety of the flight. The flight service specialist will provide, on request, the complete current METAR or SPECI for the location.

4.6.2 Traffic Circuit Procedures — Uncontrolled Airports

The following procedures apply to all aircraft operating at airports where airport control service is not provided, except those aircraft following a standard instrument approach procedure. For procedures which apply to aircraft on a standard instrument approach, refer to ATC Instrument Flight Rules — Arrival Procedures section 9. Prior to joining a traffic circuit all pilots should announce their intentions (see para 4.5.6). All turns shall be to the left while operating in the circuit, unless a right-hand circuit has been specified in the ATC section.

Pilots operating aircraft under IFR or VFR are expected to approach and land on the active runway. The active runway is a runway that other aircraft are using or are intending to use for the purpose of landing or taking off. Should it be necessary for aircraft to approach to land, or take off on a runway other than the active runway, it is expected that the appropriate communication between pilots and/or the ground station will take place to ensure there is no conflict of traffic. Some pilots operating VFR at many sites prefer to give commercial IFR and larger types of aircraft priority. This practice, however, is a personal airmanship courtesy and it should be noted that these aircraft do not establish any priority over other aircraft operating VFR at that airport.

CA 4 AIRPORT OPERATIONS

Figure 4.6 — Standard Left-Hand Circuit Pattern

NOTE:

- a. Circuit normally flown at 1,000 feet AAE.
- b. If a right-hand circuit is required in accordance with CAR 602.96, the opposite of this diagram is applicable.

a. Joining the Circuit

1. Landing and takeoff should be accomplished on the runway pointing as directly into the wind as possible, or on a runway parallel to it. However, the pilot has the final authority and responsibility for the safe operation of the aircraft, and another runway may be used if it is determined to be necessary in the interest of safety.
2. Unless otherwise specified or required by the applicable distance-from-cloud criteria, aircraft should approach the traffic circuit from the upwind side. Alternatively, once the pilot has ascertained without any doubt that there will be no conflict with other traffic entering the circuit or established within it, the pilot may also join the circuit on the downwind leg (Figure 4.6). When joining from the upwind side, the pilot should plan the descent to cross the runway in level flight at 1000 feet AAE or at the published circuit altitude and maintain that altitude until further descent is required for landing.
3. If it is necessary for an aircraft to cross the airport before joining the circuit, it is recommended that the crossover be accomplished at least 500 feet above the circuit altitude.
4. All descents should be made on the upwind side or well clear of the circuit pattern.
5. *For airports not within an MF area:* Where no MF procedures are in effect, aircraft should approach the traffic circuit from the upwind side. Alternatively, once the pilot has ascertained without any doubt that there will be no conflict with other traffic entering the

CA 4

AIRPORT OPERATIONS

circuit or traffic established within it, the pilot may join the circuit on the downwind leg (Figure 4.6).

6. *For airports within an MF area when airport advisory information is available:* Aircraft may join the circuit pattern straight in or at a 45° angle to the downwind leg, or straight in to the base or final legs (Figure 4.1). Pilots should be alert for other VFR traffic entering the circuit at these positions and for IFR straight-in or circling approaches.
7. *For airports within an MF area when airport advisory information is not available:* Aircraft should normally approach the traffic circuit from the upwind side. Alternatively, once the pilot has ascertained without any doubt that there will be no conflict with other traffic entering the circuit or traffic established within it, the pilot may join the circuit on the downwind leg (Figure 4.6), or as in subparagraph 6 above.

NOTE: When an uncontrolled airport lies within an MF area, the pilot must follow the MF reporting procedures set out in CARs 602.97 to 602.103 inclusive. (See paras 4.6.4 and 4.6.7.)

b. **Continuous Circuits**

Aircraft performing a series of circuits and landings should, after each takeoff, reach circuit altitude before joining the downwind leg.

c. **Departing the Circuit or Airport**

Aircraft departing the circuit or airport should climb straight ahead on the runway heading until reaching the circuit traffic altitude before commencing a turn in any direction to an en route heading. Turns back toward the circuit or airport should not be initiated until at least 500 feet above the circuit altitude.

4.6.3 Helicopter Operations

Pilots of helicopters at uncontrolled airports are urged to avoid air taxiing or low flying across runways and taxiway areas where risk of collision with unseen aircraft or vehicles exists.

In addition to maintaining a sharp look-out and practicing good airmanship, generally, pilots should avoid ground or air taxiing and hovering where blown dust, sand, or gravel could prove hazardous to other aircraft, or when debris could be blown onto paved surfaces.

4.6.4 Mandatory Frequency (MF)

Transport Canada has designated a Mandatory Frequency (MF) for use at selected uncontrolled airports or airports that are uncontrolled between certain hours. Aircraft operating within the area in which the MF is applicable (MF area), on the ground or in the air, shall be equipped with a functioning radio capable of maintaining two-way communication, and reporting procedures shall be followed, as specified in CARs 602.97 to 602.103 inclusive.

An MF area will be established at an airport if the traffic volume and mix of aircraft traffic at that airport is such that there would be a safety benefit derived from implementing MF procedures. There may or may not be a ground station in operation at the airport for which the MF area has been established. When a ground station is in operation, for example, an FSS, an RCO through which RAAS is provided, a CARs, or an Approach UNICOM, then all aircraft reports that are

CA 4

AIRPORT OPERATIONS

required for operating within, and prior to entering an MF area, shall be directed to the ground station. However, when the ground station is not in operation, all aircraft reports that are required for operating within, and prior to entering an MF area shall be broadcast. The MF will normally be the frequency of the ground station which provides the air traffic advisory services for the airport. For the airports with an MF, the specific frequency within which MF procedures apply will be published in Jeppesen Enroute Charts.

EXAMPLE:

- a. MF — rdo 122.2 5 NM 3100 ASL
- b. MF — UNICOM (AU) ltd hrs O/T tfc 122.75 5 NM 3100 ASL

4.6.5 Aerodrome Traffic Frequency

An Aerodrome Traffic Frequency (ATF) is normally designated for active uncontrolled airports that do not meet the criteria listed in para. 4.5.4 for an MF. The ATF is established to ensure that all radio-equipped aircraft operating on the ground or within the specified area are listening on a common frequency and following common reporting procedures. The ATF will normally be the frequency of the UNICOM where one exists or 123.2 MHz where a UNICOM does not exist. Trained vehicle operators who possess a valid radio-telephone license and are authorized to do so, can communicate with pilots using two-way communication on the ATF and provide information such as:

- a. position of vehicles on the maneuvering area;
- b. position of other aircraft on the maneuvering area; and
- c. runway condition, if known.

The specific frequency is published on the Jeppesen Airport chart (IFR airport) or Airport Directory chart (VFR airport), identified as “ATF”.

EXAMPLE: ATF — tfc 123.2 5 NM 5500 ASL

Personnel providing Approach UNICOM service, can also advise pilots on the ATF of the runway condition and position of vehicles or aircraft on the maneuvering area.

NOTE: Pilots may be able to communicate with either the UNICOM or the vehicle operator, if radio-equipped, and coordinate their arrival or departure while using normal vigilance to ensure safe operations. When communications cannot be established (no reply or NORDO) or the status of the runway is unknown, it is the pilot's responsibility to visually ascertain the runway condition before landing or taking off.

The designation of an ATF is not limited to airports only. An ATF may also be designated for use in certain areas—other than the area immediately surrounding an airport—where VFR traffic activity is high, and there is a safety benefit to ensuring that all traffic monitor the same frequency. For example, an ATF area could be established along a frequently flown corridor between two uncontrolled airports. All aircraft operating within the area, below a certain altitude, would be requested to monitor and report intentions on one frequency.

CA 4 AIRPORT OPERATIONS

4.6.6 Use of MF and ATF

When operating in accordance with VFR, or in accordance with IFR *but in visual meteorological conditions*, pilots have sole responsibility for seeing and avoiding other aircraft. Aural and visual alertness are required to enhance safety of flight in the vicinity of uncontrolled airports. At uncontrolled airports for which an MF or ATF has been designated, certain reports *shall* be made by all radio-equipped aircraft.

NOTE: Pilots operating VFR en route in uncontrolled airspace or VFR on an airway should continuously monitor 126.7 MHz when not communicating on the MF or the ATF.

Reports on either the MF or the ATF have three formats; either:

- a. a directed transmission made to a ground station;
- b. a directed transmission made to a vehicle operator on the ATF; or
- c. a broadcast transmission that is not directed to any particular receiving station.

Whenever the applicable Jeppesen Airport chart (IFR airport) or Airport Directory chart (VFR airport) indicates that reports are to be made to a ground station, the initial transmission should be made to the station. To assist in reducing frequency congestion, pilots are encouraged to use the phrase "HAVE NUMBERS" on the initial call to a ground station (arrival or departure) to indicate that they have received runway, wind and altimeter information from the previous airport advisory. When operating outside an MF area and when frequency congestion prevents pilots from making their mandatory calls, it is their responsibility to remain clear of the MF area until contact can be established with the FSS. If operating inside an MF area, the pilot should continue as stated in previous radio transmissions.

Pilot: FREDERICTON RADIO, PIPER FOXTROT X-RAY YANKEE ZULU. WE HAVE THE NUMBERS, SIX MILES SOUTHWEST AT THREE THOUSAND FIVE HUNDRED VFR. INBOUND FOR LANDING.

Should there be no acknowledgement of a directed transmission to a ground station or a vehicle operator, reports shall be made in the broadcast format unless the ground station or vehicle operator subsequently establishes two-way contact, in which case pilots shall resume communicating by directed transmission.

EXAMPLE: *Directed:* FREDERICTON RADIO, THIS IS PIPER FOXTROT X-RAY YANKEE ZULU BEACON INBOUND LANDING RUNWAY EIGHTEEN.

or

FREDERICTON VEHICLES, THIS IS PIPER FOXTROT X-RAY YANKEE ZULU...

Broadcast: FREDERICTON TRAFFIC, THIS IS PIPER FOXTROT X-RAY YANKEE ZULU...

4.6.7 VFR Communication Procedures at Uncontrolled Airports With MF and ATF Areas

- a. **Radio-equipped Aircraft**

CA 4

AIRPORT OPERATIONS

The following reporting procedures shall be followed by the pilot-in-command of radio-equipped aircraft at uncontrolled airports within an MF area, and should also be followed by the pilot-in-command at airports with an ATF:

1. *Listening Watch and Local Flying (CAR 602.97(2))* Maintain a listening watch on the mandatory frequency specified for use in the MF area. This should apply to ATF areas as well.
2. *Before Entering Maneuvering Area (CAR 602.99)* Report the pilot-in-command's intentions before entering the maneuvering area.
3. *Departure (CAR 602.100)*
 - (a) Before moving onto the take-off surface, report the pilot-in-command's departure intentions on the MF or ATF frequency. If a delay is encountered, broadcast intentions and expected length of delay, then rebroadcast departure intentions prior to moving onto the take-off surface;
 - (b) Before takeoff, ascertain by radio on the MF or ATF frequency and by visual observation that there is no likelihood of collision with another aircraft or a vehicle during takeoff; and
 - (c) After takeoff, report departing from the airport traffic circuit, and maintain a listening watch on the MF or ATF frequency until clear of the area.
4. *Arrival (CAR 602.101)*
 - (a) Report before entering the MF area, and where circumstances permit, shall do so at least five minutes before entering the area, giving the aircraft's position, altitude and estimated time of landing and the pilot-in-command's arrival procedure intentions;
 - (b) Report when joining the airport traffic circuit, giving the aircraft's position in the circuit;
 - (c) Report when on downwind leg, if applicable;
 - (d) Report when on final approach; and
 - (e) Report when clear of the surface on which the aircraft has landed.
5. *Continuous Circuits (CAR 602.102)*
 - (a) Report when joining the downwind leg of the circuit;
 - (b) Report when on final approach; stating the pilot-in-command's intentions; and
 - (c) Report when clear of the surface on which the aircraft has landed.
6. *Flying Through an MF Area (CAR 602.103)*
 - (a) Report before entering the MF or ATF area and, where circumstances permit, shall do so at least five minutes before entering the area, giving the aircraft's position and altitude and the pilot-in-command's intentions; and

CA 4

AIRPORT OPERATIONS

(b) Report when clear of the MF or ATF area.

NOTE: In the interest of minimizing possible conflict with local traffic and minimizing radio congestion on the MF or ATF, pilots of en route VFR aircraft should avoid passing through MF or ATF areas.

b. **NORDO**

NORDO aircraft will only be included as traffic to other aircraft and ground traffic as follows:

1. *Arrival* — From five minutes before the ETA until ten minutes after the ETA, and
2. *Departure* — From just prior to the aircraft departing until ten minutes after the departure, or until the aircraft is observed/reported clear of the MF area.

4.6.8 **Aircraft Without Two-Way Radio (NORDO/ONLY)**

4.6.8.1 **Prior Arrangements**

Aircraft without a functioning two-way radio may operate on the maneuvering area or within the MF area of an uncontrolled airport, provided:

- a. an FSS, a CARS or an RCO through which RAAS is provided, is located at the airport and is operating at the time proposed for the operation; and
- b. prior arrangements by telephone or in person have been made with the appropriate agency, FSS, CARS, or in the case of a RAAS, the controlling FSS.

NOTE 1: Prior arrangements for an AAS location: phone the “emergency only” number for the FSS serving the AAS location.

NOTE 2: Prior arrangements for a RAAS location:

- a. *If an FSS serves the RAAS location: phone the “emergency only” number for the FSS serving the RAAS location; or*
- b. *If an FIC serves the RAAS location: phone the number listed in Meteorology, Services and Telephone Numbers.*

When a pilot-in-command intends to operate at an uncontrolled airport for which an MF has been designated, the pilot-in-command shall ascertain by visual observations that no other aircraft or vehicle is likely to come into conflict with the aircraft during take-off or landing.

Pilots of NORDO/ONLY aircraft must be extremely vigilant when operating at either controlled or uncontrolled airports and ensure through prior arrangements that other aircraft and vehicles will be informed of their presence within the area.

4.6.8.2 **Traffic Circuits — NORDO/ONLY**

When approaching an airport, pilots of NORDO/ONLY aircraft shall enter the circuit as illustrated in Figure 4.6 and ensure that the aircraft completes at least two sides of a rectangular circuit before turning on to the final approach path.

CA 4
AIRPORT OPERATIONS

4.6.8.3 RONLY

When operating an aircraft equipped with a VHF receiver capable of receiving transmissions on the MF, pilots shall maintain a listening watch on the MF when operating on the maneuvering area or within the specified area.

4.7 AIRCRAFT GROUP NUMBER (AGN)

As a result of changes introduced to the TP312 5th Edition — AERODROME STANDARDS and RECOMMENDED PRACTICES, aeronautical publications will be updated to include information on the certification level of the various parts of the airport. This will be accomplished through the use of Aircraft Group Number or 'AGN' methodology. The purpose AGN is to provide a simple method for relating key airport technical specifications with the characteristics of the critical aircraft for which the airport or part thereof is provided. These characteristics include:

- a. Wingspan (with consideration of the aircraft approach speed category);
- b. Outer main gear span; and
- c. Tail height.

NOTE: The outer main gear width is the aircraft characteristic relating to runway and taxiway widths, wingspan relates to taxiway strip widths, and wingspan with an approach speed consideration relates to runway strip and safety area widths.

An entry of 'AGN IV' indicates that the runway is certified as meeting requirements with respect to the obstacle free environment to support the airborne and ground operation of aircraft having wingspans less than 52.12m (171 feet).

See the following table for a breakdown of wingspans into AGN groupings. The determination of the AGN is made with reference to the V_{ref} obtained with the airplane at maximum landing weight and configured with the maximum allowable landing flap. It does not include any operational adjustments to V_{ref} due to environmental conditions (steady state wind, gusts or icing, etc.) or aircraft abnormal or emergency configuration (slats or flaps jam, etc.).

Runway Obstacle Free Environment

Wing Span	Aircraft Group Number
Less than 14.94m (49')	I (for approach speed CAT C or D use AGN IIIB)
14.94m up to but not including 24.10m (79')	II (for approach speed CAT C or D use AGN IIIB)
24.10m up to but not including 36.00m (118')	IIIA (for approach speed CAT C or D use AGN IIIB)
24.10m up to but not including 36.00m (118')	IIIB (includes groups I–IIIA with C & D approach speeds)
36.00m up to but not including 52.12m (171')	IV

CA 4
AIRPORT OPERATIONS

Runway Obstacle Free Environment (continued)

Wing Span	Aircraft Group Number
52.12m up to but not including 65.23m (214')	V
65.23m up to but not including 79.86m (262')	VI

Category	A or COPTER	B	C	D	E
Speeds	up to 90 kt	91 to 120 kt	121 to 140 kt	141 to 165 kt	above 165 kt

The AGN will only be published for those taxiways having a lower AGN than of the runway with the highest certification level.

See the following table for Taxiway AGN.

Taxiway Obstacle Free Environment

Wing Span	Aircraft Group Number
Less than 14.94m (49')	I
14.94m up to but not including 24.10m (79')	II
24.10m up to but not including 36.00m (118')	IIIA / IIIB
36.00m up to but not including 52.12m (171')	IV
52.12m up to but not including 65.23m (214')	V
65.23m up to but not including 79.86m (262')	VI

- d. An Aircraft Group Number is used to communicate the maximum aircraft wingspan and approach category for the part of a certified airport that is assessed.

4.8 HELICOPTER OPERATIONS — CONTROLLED AIRPORTS

Two modes of helicopter airborne taxiing operations have been defined to accommodate the movement of helicopters at controlled airports; these are HOVER TAXI and AIR TAXI.

Hover Taxi is the movement of a helicopter above the surface of an airport, in ground effect, and at airspeeds less than approximately 20 KIAS. The actual height may vary; some helicopters require hover taxi above 25 ft AGL to reduce ground effect turbulence or provide clearance for cargo slingloads.

Air Taxi is the movement of a helicopter above the surface of an airport normally below 100 ft AGL. The pilot is solely responsible for selecting an appropriate height and airspeed for the operation being conducted and consistent with existing traffic and weather conditions. Pilots are cautioned of the possibility of the loss of visual references when conducting air taxi operations. Because of the greater operating flexibility, an air taxi clearance is to be expected unless traffic conditions will not permit this mode of operation.

CA 4
AIRPORT OPERATIONS

When a helicopter is wheel-equipped and the pilot wishes to taxi on the ground, ATC should be informed when the clearance is requested.

NOTE: Helicopter pilots are reminded that aircraft, vehicle and personnel movements are not controlled on airport aprons and that caution must be exercised at all times during any surface movement, hover or air taxiing.

CA 5
VFR EN ROUTE PROCEDURES

SECTION 5

5.1 MONITORING 126.7 MHz AND POSITION REPORTING ENROUTE

Pilots operating Visual Flight Rules (VFR) enroute in uncontrolled airspace when not communicating on a Mandatory Frequency (MF) or an Aerodrome Traffic Frequency (ATF), or VFR on an airway should continuously monitor 126.7 MHz. and whenever practicable, broadcast their identification, position, altitude and intentions on this frequency to alert other VFR or IFR aircraft that may be in the vicinity. Although it is not mandatory to monitor 126.7 MHz and broadcast reports during VFR or VFR-OTT flights, pilots are encouraged to do so for their own protection.

Pilots are encouraged to make position reports on the appropriate FISE frequency to an FIC where they are recorded by the flight service specialist and are immediately available in the event of SAR action. The following format is recommended:

- a. Identification
- b. Position
- c. Time over
- d. Altitude
- e. VFR/VFR-OTT
- f. Destination

EXAMPLE:

Pilot: QUEBEC RADIO, THIS IS CESSNA GOLF INDIA GOLF BRAVO ON THE GATINEAU R-C-O, VFR (or VFR OVER-THE-TOP) POSITION REPORT.

Radio: CESSNA GOLF INDIA GOLF BRAVO, QUEBEC RADIO, GO AHEAD.

Pilot: QUEBEC RADIO, GOLF INDIA GOLF BRAVO, BY OTTAWA AT FIVE EIGHT, FOUR THOUSAND FIVE HUNDRED, VFR (or VFR OVER-THE-TOP), DESTINATION SUDBURY.

NOTE 1: As shown in the example it is important on initial contact that the pilot alerts the FIC to the fact that it is a VFR or VFR-OTT position report and indicates the name of the location of the RCO followed by the letters R-C-O in a non-phonetic form.

NOTE 2: The ETA destination or next reporting point may be included.

NOTE 3: Under certain conditions position reports are required prior to entering the ADIZ when operating on a DVFR flight plan or a defence flight itinerary. (See ATC 2.13 and 3.9.)

5.2 ACKNOWLEDGEMENT OF CLEARANCES

Pilots of VFR flights shall read back the text of an ATC clearance when requested by an ATC unit.

CA 5

VFR EN ROUTE PROCEDURES

5.3 ALTITUDES AND FLIGHT LEVELS – VFR

Aircraft shall be operated at altitudes or flight levels appropriate to the direction of flight when in level cruising flight above 3000 ft AGL.

5.4 MINIMUM ALTITUDES – VFR (CARs 602.14 AND 602.15)**Minimum Altitudes and Distances***CAR 602.14*

- (1) This Subsection was repealed on 2003/03/01.
- (2) Except where conducting a takeoff, approach or landing or where permitted under section 602.15, no person shall operate an aircraft
 - (a) over a built-up area or over an open-air assembly of persons unless the aircraft is operated at an altitude from which, in the event of an emergency necessitating an immediate landing, it would be possible to land the aircraft without creating a hazard to persons or property on the surface, and, in any case, at an altitude that is not lower than
 - (i) for aeroplanes, 1000 feet above the highest obstacle located within a horizontal distance of 2000 feet from the aeroplane,
 - (ii) for balloons, 500 feet above the highest obstacle located within a horizontal distance of 500 feet from the balloon, or
 - (iii) for an aircraft other than an aeroplane or a balloon, 1000 feet above the highest obstacle located within a horizontal distance of 500 feet from the aircraft; and
 - (b) in circumstances other than those referred to in paragraph (a), at a distance less than 500 feet from any person, vessel, vehicle or structure.

Permissible Low Altitude Flight*CAR 602.15*

- (1) A person may operate an aircraft at altitudes and distances less than those specified in subsection 602.14(2) where the aircraft is operated at altitudes and distances that are no less than necessary for the purposes of the operation in which the aircraft is engaged, the aircraft is operated without creating a hazard to persons or property on the surface and the aircraft is operated
 - (a) for the purpose of a police operation that is conducted in the service of a police authority;
 - (b) for the purpose of saving human life;
 - (c) for firefighting or air ambulance operations;
 - (d) for the purpose of the administration of the Fisheries Act or the Coastal Fisheries Protection Act;
 - (e) for the purpose of the administration of the national or provincial parks; or

CA 5
VFR EN ROUTE PROCEDURES

- (f) for the purpose of flight inspection.
- (2) A person may operate an aircraft, to the extent necessary for the purpose of the operation in which the aircraft is engaged, at altitudes and distances less than those set out in
- (a) paragraph 602.14(2)(a), where operation of the aircraft is authorized under Subpart 3 or section 702.22; or
 - (b) paragraph 602.14(2)(b), where the aircraft is operated without creating a hazard to persons or property on the surface and the aircraft is operated for the purpose of
 - (i) aerial application or aerial inspection,
 - (ii) aerial photography conducted by the holder of an air operator certificate,
 - (iii) helicopter external load operations, or
 - (iv) flight training conducted by or under the supervision of a qualified flight instructor.

NOTE: The hazards of low flying cannot be over emphasized. In addition to the normal hazards of low flying, such as impact with the ground, two issues regarding man-made structures should be stressed.

- a. All obstructions extending 300 ft AGL or higher, or lower if deemed hazardous by TC, will be charted on VNCs and VTAs.*

New obstructions, correctly reported by the owner to TC and NAV CANADA, will be NOTAMed and inserted in the CFS and eventually (next edition) charted on the applicable VNC and VTA. (Pilots noting obstructions not depicted are asked to alert TC.)

- b. Wire-strikes account for a significant number of low flying accidents. A number of these accidents occur over level terrain, in good weather and at very low altitudes.*

The regulations governing low level flight are located in several areas of the CARs. It is the responsibility of the pilots and the companies they work for to ensure that all regulations are strictly adhered to.

5.5 MINIMUM ALTITUDES – OVERFLYING AERODROMES [CARs 602.96(4) AND (5)]

CAR 602.96

- (4) Unless otherwise authorized by the appropriate air traffic control unit, no pilot-in-command shall operate an aircraft at a height of less than 2000 feet over an aerodrome except for the purpose of landing or taking off or if the aircraft is operated pursuant to subsection (5).

CAR 602.96

- (5) Where it is necessary for the purposes of the operation in which the aircraft is engaged, a pilot-in-command may operate an aircraft at less than 2000 feet over an aerodrome, where it is being operated
- (a) in the service of a police authority;

CA 5
VFR EN ROUTE PROCEDURES

- (b) for the purpose of saving human life;
- (c) for fire-fighting or air ambulance operations;
- (d) for the purpose of the administration of the Fisheries Act or the Fisheries Protection Act;
- (e) for the purpose of the administration of the national or provincial parks;
- (f) for the purpose of flight inspection;
- (g) for the purpose of aerial application or aerial inspection;
- (h) for the purpose of highway or city traffic patrol;
- (i) for the purpose of aerial photography conducted by the holder of an air operator certificate;
- (j) for the purpose of helicopter external load operations; or
- (k) for the purpose of flight training conducted by the holder of a flight training unit operator certificate.

5.6 CONTROLLED VFR (CVFR) PROCEDURES

Pilots intending to fly CVFR shall file a flight plan and obtain an ATC clearance prior to entering Class B airspace. The ATC clearance will not normally be issued prior to takeoff unless the airspace within a control zone is Class B. The ATC clearance will normally be issued upon receipt of a position report filed by the pilot upon reaching the last 1000 ft altitude below the base of Class B or before entering laterally. This procedure is intended to ensure that the radio equipment is operating and to remind the pilots that while outside of Class B airspace ATC separation is not provided and that they must maintain a vigilant watch for other traffic. The ATC clearance will contain the phrase "MAINTAIN (altitude) VFR".

CVFR flights must be conducted in accordance with procedures designed for use by IFR flights, except that when IFR weather conditions are encountered, the pilot of a CVFR flight must avoid such weather conditions. This should be accomplished by:

- a. requesting an amended ATC clearance which will enable the aircraft to remain in VFR weather conditions.
- b. requesting an IFR clearance if the pilot has a valid instrument rating and the aircraft is equipped for IFR flight.
- c. request special VFR if within a control zone.

If unable to comply with the preceding, ensure that the aircraft is in VFR weather conditions at all times and leave Class B airspace horizontally or by descending. If the airspace is a control zone, land at the aerodrome on which the control zone is based. In both cases, inform ATC as soon as possible of the action taken.

CA 5

VFR EN ROUTE PROCEDURES

5.7 ENROUTE RADAR SURVEILLANCE

When operating in areas where radar coverage exists, VFR flights with transponder equipped aircraft may request radar traffic information. ATC will provide this information, traffic (or workload) permitting (see ATC 1.5.3).

The service is provided by the ACC or TCU responsible for IFR control service in the area(s) concerned. The appropriate frequency for the controlling ATC unit may be found on the Jeppesen Airport chart (nearest controlled airport), enroute (IFR) charts or by request to a FIC.

PHRASEOLOGY:

“REQUEST RADAR SURVEILLANCE”

EXAMPLE: “EDMONTON ADVISORY, CESSNA SKYLANE FOXTROT ALPHA BRAVO CHARLIE, TEN NORTHEAST OF CAMROSE AT 6500 VFR SQUAWKING 1200 ENROUTE TO VILLENEUVE; REQUEST RADAR SURVEILLANCE.”

5.8 VFR OPERATIONS WITHIN CLASS C AIRSPACE

The following are the basic procedures for entry into, and for operation within Class C airspace. Pilots should consult the applicable VTA chart for any additional procedures that may be required for that particular Class C airspace.

a. Pilot Procedures

1. Obtain ATIS information (when available) prior to contacting ATC.
2. Contact ATC on VFR advisory frequency (depicted on VTA charts) prior to entry into Class C airspace and provide the following information:
 - aircraft type and identification
 - position (preferably over a call-up point depicted on the VTA chart or a bearing and distance from it, otherwise another prominent reporting point or a VOR radial or VOR/DME fix)
 - altitude
 - destination and route
 - transponder code (if transponder equipped), and ATIS (code) received.
3. Comply with ATC instructions received. Any ATC instruction issued to VFR flights is based on the firm understanding that a pilot will advise ATC immediately if compliance with the instructions would result in not being able to maintain adequate terrain or obstacle clearance, or to maintain flight in accordance with VFR. If so advised, ATC will issue alternate instructions.

b. ATC Procedures

1. Identify the aircraft with radar. (Pilots may be required to report over additional fixes, or squawk ident on their transponder.) The provision of an effective radar service is dependent upon communications equipment capabilities and the adequacy of the radar displayed information. In the latter case, it may be difficult to maintain radar identifica-

CA 5
VFR EN ROUTE PROCEDURES

tion of aircraft which are not operating on specific tracks or routes (i.e., sightseeing, local training flights, etc.), and pilots will be advised when radar service cannot be provided.

2. Issue landing information on initial contact or shortly thereafter unless the pilot states that the appropriate ATIS information has been received.
3. Provide the aircraft with routing instructions or radar vectors whenever necessary. The pilot will be informed when vectoring is discontinued except when transferred to a tower. Occasionally, an aircraft may be held at established fixes within Class C airspace to await a position in the landing sequence.
4. Issue traffic information when two or more aircraft are held at the same fix, or whenever in the controller's judgement a radar-observed target might constitute a hazard to the aircraft concerned.
5. When required, conflict resolution will be provided between IFR and VFR aircraft, and upon request, between VFR aircraft.
6. Visual separation may be effected when the pilot reports sighting a preceding aircraft and is instructed to follow it.
7. Inform the pilot when radar service is terminated, except when the aircraft has been transferred to a tower.

CA 6
INSTRUMENT FLIGHT RULES -- GENERAL

SECTION 6

6.1 ATC CLEARANCE

Air traffic control (ATC) clearance shall be obtained before takeoff from any point within controlled airspace or before entering controlled airspace for flight under instrument flight rules (IFR) or during instrument meteorological conditions (IMC).

According to *Canadian Aviation Regulation (CAR)* 602.31, clearance received by a pilot must be read back to the controller, except in certain circumstances. When the clearance is received on the ground, before departing a controlled airport, and a Standard Instrument Departure (SID) is included in the clearance, the pilot only needs to acknowledge receipt of the clearance by repeating the aircraft call sign and the transponder code that was assigned. If there is an amendment to the altitude contained in the SID, that altitude shall also be read back. Whenever the controller requests a full readback, the pilot shall comply. Also, the pilot may, at any time, read back a clearance in full to seek clarification.

Whenever a clearance is received and accepted by the pilot, the pilot shall comply with the clearance. If a clearance is not accepted, the pilot shall immediately notify ATC, because simple acknowledgement of the clearance will be interpreted by the controller as acceptance.

Pilots shall not deviate from a clearance except in an emergency that necessitates *immediate* action, or in order to respond to an airborne collision avoidance system/traffic alert and collision avoidance system (ACAS/TCAS) resolution advisory (RA), a warning from a Ground Proximity Warning System (GPWS), or a warning from an aircraft wind shear (WS) detection and warning system (see METEOROLOGY — PILOT REPORTS — Wind Shear). In these cases, the pilot shall inform ATC as soon as possible and obtain an amended clearance. (CAR 602.31)

6.2 IFR FLIGHTS IN VMC

A pilot may elect to conduct a flight in accordance with IFR in VMC. Flights operating in accordance with IFR shall continue in accordance with IFR, regardless of weather conditions. An IFR clearance provides separation between IFR aircraft in controlled airspace only. Pilots operating IFR must be aware of the need to provide their own visual separation from VFR aircraft when operating in VMC and from any other aircraft when operating in uncontrolled airspace.

A pilot may cancel IFR or close the IFR flight plan provided the aircraft is operating in VMC, is outside Class A or B airspace, and it is expected that the flight will not return to IMC. If the pilot closes the IFR flight plan or cancels IFR, ATC will discontinue the provision of IFR control service.

Refer to ATC 3.12.2 for information on the requirement to submit an arrival report and on the provision of alerting service upon closure or cancellation of IFR. Provided the destination remains the same, a pilot may change an IFR flight plan to a VFR flight plan without having to file a new flight plan. ATS will, however, confirm the aircraft's destination, ETA, and obtain a search and rescue time from the pilot.

6.2.1 IFR Clearance with VFR Restrictions

ATC may issue an IFR clearance for an aircraft to depart, climb or descend VFR until a specified time, altitude, or location provided:

CA 6

INSTRUMENT FLIGHT RULES -- GENERAL

- a. the pilot requests it;
- b. the aircraft is outside Class A airspace;
- c. the aircraft is within Class B airspace at or below 12,500 ft ASL or within Class C, D or E airspace; and
- d. the weather conditions permit.

Pilots are reminded that during such a VFR restriction they must provide their own separation, including wake turbulence separation, from other IFR aircraft as well as from the VFR traffic. Controllers normally issue traffic information concerning other IFR aircraft, particularly in marginal weather conditions. If compliance with the restriction is not possible, the pilot should immediately advise ATC and request an amended clearance.

6.2.2 VFR Release of an IFR Aircraft

When a delay is experienced in receiving an IFR departure clearance, a pilot may request approval to depart and maintain VFR until an IFR clearance can be received. The conditions in para 6.2.1 also apply in this situation. If the request for a VFR departure is approved, the pilot will be given a time, altitude or location at which to contact ATC for an IFR clearance. Depending upon the reasons for the IFR departure clearance delay, a VFR departure of an IFR flight may not be approved by the IFR unit. In situations such as these, it may be desirable for the pilot to wait for the IFR departure clearance.

6.3 EMERGENCIES AND EQUIPMENT FAILURES — IFR

6.3.1 Declaration of Emergency

Whenever pilots are faced with an emergency situation, ATC expects the pilot to take whatever action is considered necessary. ATC will assist pilots in any way possible whenever an emergency is declared. Pilots are requested to advise ATC of any deviations from IFR altitudes or routes necessitated by an emergency situation as soon as it is practicable, in order that every effort can be made to minimize confliction with other aircraft.

Pilots of transponder-equipped aircraft, when experiencing an emergency and unable to establish communications immediately with an ATC unit, may indicate "Emergency" to ATC by adjusting the transponder to reply to Mode A/3 Code 7700. Thereafter, radio communications should be established with ATC as soon as possible.

It should be pointed out, however, that when Code 7700 is used, the signal may not be detected because the aircraft may not be within the range of SSR coverage.

6.3.2 Two-Way Communications Failure

It is impossible to provide regulations and procedures applicable to all possible situations associated with two-way communications failure. During a communications failure, when confronted by a situation not covered in the regulations, pilots are expected to exercise good judgment in whatever action they elect to take. The following procedures are the standard communications failure procedures; however, they may be superseded by specific procedures that take precedence. For

CA 6
INSTRUMENT FLIGHT RULES -- GENERAL

example, some missed approach and SID procedures may have specific published communications failure procedures.

6.3.2.1 General

Unless otherwise authorized by ATC, the pilot-in-command of an aircraft that experiences a two-way communications failure when operating in or cleared to enter controlled airspace under IFR, or when operating in or cleared to enter Class B or C airspace under VFR shall:

- a. select the transponder to reply to Mode A/3 Code 7600 interrogations, if the aircraft is transponder-equipped;
- b. maintain a listening watch on appropriate frequencies for control messages or further clearances; acknowledge receipt of any such messages by any means available, including the use of approved satellite voice equipment or the selective use of the normal/standby functions of transponders;
- c. attempt to contact any ATC facility or another aircraft, inform them of the difficulty, and request they relay the information to the ATC facility with whom communications are intended;
- d. comply with the procedures specified by the Minister except where specific instructions to cover an anticipated communications failure have been received from an ATC unit; and
- e. attempt to contact the appropriate NAV CANADA ATS unit by means of a conventional cell or satellite phone, when all of the above attempts have failed.

NOTE: Approved SATCOM voice equipment refers to on board embedded equipment. Permanent satellite voice equipment is installed and tested in accordance with appropriate certification and airworthiness standards.

6.3.2.2 IFR Flight Plan

- a. **Visual Meteorological Conditions (VMC):** If the failure occurs in VMC, or if VMC are encountered after the failure, the pilot-in-command shall continue the flight under VFR and land as soon as practicable.

NOTE: This procedure applies in any class of airspace. The primary purpose is to preclude extended IFR operation in controlled airspace in VMC. However, it is not intended that the requirement to "land as soon as practicable" be construed to mean "land as soon as possible". The pilot retains the prerogative of exercising his/her best judgment and is not required to land at an unauthorized airport, at an airport unsuitable for the type of aircraft flown, or to land only minutes short of destination.

- b. **Instrument Meteorological Conditions (IMC):** If the failure occurs in IMC, or if the flight cannot be continued under VMC, the pilot-in-command shall continue the flight according to the following:

1. *Route* —

- (a) by the route assigned in the last ATC clearance received and acknowledged;

CA 6
INSTRUMENT FLIGHT RULES -- GENERAL

- (b) if being radar vectored, by the direct route from the point of communications failure to the fix, route, or airway specified in the vector clearance;
 - (c) in the absence of an assigned route, by the route that ATC has advised may be expected in a further clearance; or
 - (d) in the absence of an assigned route or a route that ATC has advised may be expected in a further clearance, by the route filed in the flight plan.
2. *Altitude* — At the HIGHEST of the following altitudes or flight levels for the ROUTE SEGMENT BEING FLOWN:

- (a) the altitude(s) or flight level(s) assigned in the last ATC clearance received and acknowledged;
- (b) the minimum IFR altitude (see ATC 8.6.1); or
- (c) the altitude or flight level ATC has advised may be expected in a further clearance. (The pilot shall commence climb to this altitude/FL at the time or point specified by ATC to expect further clearance/altitude change.)

NOTE 1: The intent of the above is that an aircraft which has experienced communications failure will, during any segment of a flight, be flown at an altitude that provides the required obstacle clearance.

NOTE 2: If the failure occurs while being vectored at a radar vectoring altitude which is lower than a published IFR altitude, then the pilot shall immediately climb to and maintain the appropriate minimum IFR altitude until arrival at the fix, route or airway specified in the clearance.

3. *Descent for Approach* — Maintain enroute altitude to the navigation facility or the approach fix to be used for the instrument approach procedure selected and commence an appropriate descent procedure at whichever of the following times is the most recent:
- (a) the ETA [ETA as calculated from take-off time plus the estimated time en route filed or amended (with ATC)];
 - (b) the ETA last notified to and acknowledged by ATC; or
 - (c) the expected approach time (EAT) last received and acknowledged.

If failure occurs after you have received and acknowledged a holding instruction, hold as directed and commence an instrument approach at the EAT or expected further clearance time, whichever has been issued.

NOTE 1: If the holding fix is not a fix from which an approach begins, leave the fix at the expected further clearance time if one has been received. If none has been received, proceed to a fix from which an approach begins upon arrival over the clearance limit. Commence descent and/or approach as close as possible to the estimated time of arrival as calculated from the filed estimated time enroute or as amended with ATC.

CA 6
INSTRUMENT FLIGHT RULES -- GENERAL

NOTE 2: If cleared for a standard terminal arrival (STAR), maintain the appropriate altitude described in para 6.3.2.2 b. and proceed to the final approach fix (FAF):

- a. via the published routing;*
- b. via the published routing to the segment where radar vectors are depicted to commence, then direct to the facility or fix serving the runway advised by ATIS or specified in the ATC clearance, for a straight-in approach, if able, or for the full procedure if one is published;*
- c. for a CLOSED RNAV STAR, by flying the arrival as published, including any vertical and speed restraints depicted in the procedure, and intercepting the final approach course for a straight-in approach; or*
- d. for an OPEN RNAV STAR, by flying the arrival as published, including any vertical and speed restraints depicted in the procedure. The pilot is expected to delete the heading leg at the downwind termination waypoint (DTW), to initiate an auto-turn at the DTW and final approach course fix (FACF) and to intercept the final approach course for a straight-in approach.*

For flights to the United States, communication failure procedures are essentially the same, but it is the pilot's responsibility to consult the appropriate American publications.

Some instrument procedures do not include a procedure turn, but include the statement "RADAR OR RNAV REQUIRED" as part of the procedure. The initial approach segment of these instrument procedures is being provided by ATC radar vectors. Without ATC radar vectoring, the instrument procedure may not have a published initial approach segment.

Should an aircraft communications failure occur while being vectored on one of these approaches, separately or as part of a STAR, the pilot is expected to comply with the communications failure procedure by selecting the transponder to Mode A/3 Code 7600 immediately. Pilots should always be aware of the traffic situation. For example, ATC may have indicated that your aircraft was second for an approach to Runway 06L; under these circumstances, the flight should be continued along the route that normally would have been expected under radar vectoring. In some cases of communications failure, pilots may need to revert to dead reckoning navigation (DR) to the final approach course. It is important to other aircraft and ATC for the aircraft experiencing a communications failure to continue the flight along a route that would permit the aircraft to conduct a straight-in approach and landing without unexpected maneuvering. Pilots are expected to exercise good judgment in these cases. Unexpected maneuvers, such as turns away from the final approach course, may cause traffic disruptions and conflicts.

If the communications failure occurs while being vectored at a radar vectoring altitude which is lower than a published IFR altitude (i.e., Minimum Sector Altitude 25 NM), the pilot shall immediately climb to and maintain the appropriate minimum IFR altitude until arrival at a fix associated with the instrument procedure.

Modern technology has introduced new on board communications capabilities, such as airborne telephone communications. Pilots who are confronted with an aircraft communications failure may, if circumstances permit, use this new on board technology to establish communications with the appropriate ATC units. Phone numbers of ACCs, control towers, FICs and FSSs are listed in Meteorology and Airport Directory.

CA 6
INSTRUMENT FLIGHT RULES -- GENERAL

6.3.3 Reporting Malfunctions of Navigation and Communications Equipment

The pilot-in-command of an aircraft in IFR flight within controlled airspace should report immediately to the appropriate ATC unit any malfunction of navigation or air-to-ground communications equipment.

EXAMPLE 1: Loss of VOR, ADF or low frequency navigation capability.

EXAMPLE 2: Complete or partial loss of ILS capability.

EXAMPLE 3: Impairment of air-to-ground communications capability.

EXAMPLE 4: Impairment of transponder serviceability.

Having received this information, ATC will take into account any limitations in navigation or air-to-ground communications equipment in further clearances to the aircraft.

6.3.4 Fuel Dumping

Whenever it is necessary to jettison fuel, the pilot should immediately notify ATC and provide information such as the course to be flown, the period of time and weather conditions. To allow for adequate vaporization, fuel dumping should be carried out at least 2000 ft above the highest obstacle within 5 NM of the track to be flown. ATC may suggest an alternate area where fuel should be dumped; aircraft will be encouraged to dump fuel on a constant heading over unpopulated areas and clear of heavy traffic. When necessary information has been obtained, ATC will broadcast on appropriate frequencies a "fuel dumping" advisory. Pilots should advise ATC immediately when fuel dumping has been completed.

6.4 IFR SEPARATION

6.4.1 General

The following information is intended to acquaint pilots with some of the basic non-radar separation standards applied by ATC and so facilitate flight planning and understanding of ATC techniques.

6.4.2 Vertical Separation — General

The standard vertical separation minima is as follows: FL290 and below — 1000 ft; above FL290 — 2000 ft.

6.4.3 Vertical Separation Between Flight Levels and Altitudes ASL

When the altimeter setting is less than 29.92" Hg, there will be less than 1000 ft vertical separation between an aircraft flying at 17,000 ft ASL with that altimeter setting and an aircraft flying at FL180 (with altimeter set at 29.92" Hg); therefore, the lowest usable flight level will be assigned or approved in accordance with the following table:

CA 6
INSTRUMENT FLIGHT RULES -- GENERAL

Altimeter Setting	Lowest Usable Flight level
29.92" or higher	FL180
29.91" to 28.92"	FL190
28.91" to 27.92"	FL200

6.4.4 Longitudinal Separation — Distance-based

Longitudinal separation of IFR flights based on distance is established by ATC on the basis of position reports, expressed in units of distance, from the concerned aircraft determined in relation to a common point. To account for the effect of slant range, controllers must know when distance reports are derived from DME when establishing longitudinal separation between a mix of RNAV/GPS and DME-equipped aircraft.

To this end, pilots should report distances based on RNAV and GPS in miles, e.g. 30 miles from "Someplace." When distance reports are based on DME, pilots should state DME, e.g. 30 DME from "Someplace."

NOTE: RNAV position reports derived from DME – DME computations are not affected by slant range.

6.4.5 Lateral Separation — General

Lateral separation of IFR flights is provided by ATC in the form of "airspace to be protected" in relation to a holding procedure, instrument approach procedure or the approved track. The dimensions of protected airspace for a particular track take into account the accuracy of navigation that can reasonably be expected. For track segments within signal coverage of NDB, VOR or TACAN stations and along bearings/courses/radials of such facilities, protected airspace takes into account the accuracy of available track guidance, accuracy of airborne receiver and indicator equipment, and a small pilotage tolerance. Separation is considered to exist provided the airspaces protected for each aircraft do not overlap. It is essential, therefore, that accuracy capability of navigation equipment be maintained.

Pilots of IFR or controlled VFR flights must adhere as closely as practicable to the center line of their approved airway or track. If the aircraft inadvertently deviates from the approved track, immediate action must be taken to regain the center line as soon as practicable. Pilots realizing that they are outside the airspace protected for their approved track must notify the appropriate ATC unit immediately.

6.4.6 Lateral Separation — Airways and Tracks

In the low level airspace, the airspace to be protected is the full width of the airway as illustrated in ATC 2.7.1.

In the high level airspace, all airspace is controlled within the Southern, Northern, and Arctic Control Areas. As a result, a high level airway is "a prescribed track between specified radio aids to navigation" and, thus, has no defined lateral dimensions. Therefore, the airspace to be protected for airways and/or tracks in the high level airspace is the same as that for low level airways.

CA 6
INSTRUMENT FLIGHT RULES -- GENERAL

Along off-airway tracks the "airspace to be protected" is 45 NM each side of that portion of the track which is beyond navigational and signal coverage range.

Figure 6.1 — Airspace to be Protected Along Off-Airway Tracks

Figure 6.2 — Additional Airspace to be Protected for Turns

Additional airspace will be protected at and above FL180 on the maneuvering side of tracks which change direction by more than 15° overhead navigation aids or intersections. It is expected that pilots of aircraft operating below FL180 will make turns so as to remain within the normal width of airways or airspace protected for off-airway tracks.

Normally, the airspace to be protected for an approved track will be based on the premise that the changeover from one navigation reference to another will take place approximately midway between facilities. Where this is not possible due to a difference in the signal coverage provided by two adjacent navigation aids, the equal signal point on an airway segment will be shown.

To remain clear of restricted areas, active danger or alert areas, or active areas such as the Churchill Rocket Range, pilots should file a flight plan so that the airspace-to-be-protected for the intended track does not overlap the area of concern.

CA 6

INSTRUMENT FLIGHT RULES -- GENERAL

6.4.7 Lateral Separation – Instrument Approach Procedures

Air traffic controllers have been authorized to consider the basic horizontal dimensions of intermediate approach areas, final approach areas and missed approach areas, for obstacle clearance purposes, as the airspace-to-be-protected for aircraft conducting standard instrument approach procedures. Adequate horizontal separation is then deemed to exist when the airspace-to-be-protected for such aircraft does not overlap the airspace-to-be-protected for aircraft enroute, holding or conducting simultaneous adjacent instrument approaches.

As with other separation standards based on the airspace-to-be-protected concept, it will be the pilot's responsibility to remain within the limits of airspace-to-be-protected. This can be accomplished by following the procedures published by Jeppesen or approved for company use. If a pilot operating in controlled airspace anticipates being unable to conduct the approach as published, the pilot should inform ATC so that separation from other aircraft concerned can be increased as necessary.

6.5 VISUAL SEPARATION**6.5.1 General**

Visual separation is a means of separating IFR aircraft using visual observation and is performed by an airport controller or by a pilot, when a pilot is assigned responsibility for separation. Visual separation may be applied in a CZ or TCA at 12,500 ft ASL and below.

6.5.2 Speed Control Instructions on Departure

Visual departure separation procedures require airport controllers to consider aircraft performance, wake turbulence, closure rate, routes of flight and known weather conditions. Airport controllers do not issue speed control instructions coincident with takeoff clearances. In addition, there is no increase in the incidence of speed control instructions issued by the departure controller.

6.5.3 Controller-Applied Visual Separation

The airport controller ensures separation through visual observation of the aircraft involved. This type of visual separation cannot be applied if departure routes or aircraft performance preclude maintaining separation. ATC does not use visual separation between successive departing IFR aircraft if wake turbulence separation is required. Controller-applied visual separation is normally seamless to pilots.

6.5.4 Pilot-Applied Visual Separation

Pilot-applied visual departure separation procedures require a pilot to see the other aircraft involved and, upon instructions from the controller, maintain visual separation from the other aircraft.

Pilots who accept responsibility for visual separation must maintain constant visual contact, without referring to an airborne surveillance system, with the other aircraft involved until visual separation is discontinued. This responsibility does not eliminate the pilot's regulatory responsibility to see and avoid other aircraft; meet noise abatement requirements; or meet obstacle clearance requirements and is not intended to restrict pilots from completing other necessary tasks.

CA 6

INSTRUMENT FLIGHT RULES -- GENERAL

ATC does not use pilot-applied visual separation between successive departing IFR aircraft if wake turbulence separation is required. If, for any reason, the pilot refuses pilot-applied visual separation, ATC will separate departures using another form of IFR separation.

Example phraseology for pilot-applied visual departure separation:

- Tower: AIRLINE ONE TWO THREE, TRAFFIC (position, type of aircraft, intentions, etc.) CONFIRM TRAFFIC IN SIGHT?
- Pilot: AIRLINE ONE TWO THREE, TRAFFIC IN SIGHT.
- Tower: AIRLINE ONE TWO THREE, MAINTAIN VISUAL SEPARATION CLEARED FOR TAKEOFF (other information or instructions, as required).
- Pilot: AIRLINE ONE TWO THREE, MAINTAINING VISUAL SEPARATION (read back additional instructions, as appropriate).

Visual separation is discontinued when either aircraft is observed on a diverging heading, unless otherwise advised by ATC.

Pilots must notify ATC as soon as possible if:

- they anticipate losing sight of the other aircraft;
- course deviations are required to maintain visual separation with preceding traffic; or
- they suspect they will be unable to maintain visual separation for any reason.

In these cases, another form of IFR separation will be applied by ATC.

6.6 DEVELOPMENT OF INSTRUMENT PROCEDURES

Instrument procedure development worldwide follows one of two existing standards: *ICAO Procedures for Air Navigation Services – Aircraft Operations, Volume II — Construction of Visual and Instrument Flight Procedures* (Doc 8168); or the *United States Standard for Terminal Instrument Procedures* (TERPS). Instrument procedures in Canadian domestic airspace are developed in accordance with a document entitled, *Criteria for the Development of Instrument Procedures* (TP 308). This document is a joint TC/DND publication and prescribes standardized methods for use in designing both civil and military instrument flight procedures.

In order to achieve ICAO regional commonality, the instrument procedure design standards and criteria contained in TP 308 are modeled after the standards and criteria contained in the TERPS.

Strict adherence by pilots to the published instrument procedures will ensure an acceptable level of safety in flight operations.

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

SECTION 7

7.1 AIRPORT OPERATIONS

Pilots should read ATC 4.2 to 4.5 in conjunction with the IFR departure procedures listed in this section.

7.2 ATIS BROADCASTS

If available, the basic airport information should be obtained from ATIS prior to requesting taxi clearance.

7.3 INITIAL CONTACT

On initial contact with ATC (clearance delivery or ground control), a pilot departing IFR should state the destination and planned initial cruising altitude.

7.4 IFR CLEARANCES

At locations where a "Clearance Delivery" frequency is listed, pilots should obtain their IFR clearance on this frequency prior to contacting ground control. Where no clearance delivery frequency is listed, the IFR clearance will normally be relayed by ground control after taxi authorization has been issued. However, due to high fuel consumption during ground running time, some pilots of turbojet aircraft may wish to obtain their IFR clearance prior to starting engines. Pilots using this procedure should call ATC, using a phrase such as "READY TO START NOW" or "READY TO START AT (time)." Normally this request should be made within five minutes of the planned engine start time.

New technology available in some control towers permits the electronic delivery of initial IFR clearances via air-ground data link (AGDL). This new delivery method is known as pre-departure clearance (PDC) and is available to those airline companies with an on-site computer capable of interfacing with ATC and the data link service provider.

7.5 STANDARD INSTRUMENT DEPARTURE (SID)

At certain airports, an instrument flight rules (IFR) departure clearance may include departure instructions known as a standard instrument departure (SID). A SID is a planned IFR air traffic control (ATC) departure procedure published for pilot and controller use in graphic and textual form. SIDs provide a transition from the terminal to the appropriate enroute structure, and may be either:

- a. **pilot navigation SIDs** — established where the pilot is required to use the chart as reference for navigation to the enroute phase; or
- b. **vector SIDs** — established where ATC will provide radar navigational guidance to a filed/assigned route or to a fix depicted on the chart. Pilots are expected to use the SID chart as reference for navigation until radar vectoring is commenced.

SIDs incorporate obstacle and terrain clearance within the procedure. Pilots should note, however, that SIDs for military airports that are only available in textual form do not incorporate obsta-

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

cle and terrain clearance. At these airports, it is the pilot's responsibility to ensure appropriate obstacle and terrain clearance on departure.

Pilots of aircraft operating at airports for which SIDs have been published will normally be issued a SID clearance by ATC. No pilot is required to accept a SID clearance. If any doubt exists as to the meaning of such a clearance, the pilot should request a detailed clearance.

Routings contained in SIDs will normally be composed of two segments:

- a. an initial segment from the departure end of the runway to the position where the aircraft will first turn from the initial departure heading; and
- b. a second segment, either via radar vectors or by pilot navigation, from the first turning point to the SID termination point.

When instructed to fly runway heading or when flying a SID for which no specific heading is published, pilots are expected to fly or maintain the heading that corresponds with the extended center line of the departure runway until otherwise instructed by ATC. Drift correction must not be applied; e.g. Runway 04, if the actual magnetic heading of the runway center line is 044 degrees, then fly a heading of 044 degrees M.

When flying a SID for which a specific heading is published, the pilot is expected to steer the published SID heading until radar vectoring commences. This is because initial separation is based on divergence between assigned headings until radar separation is established.

When assigning SIDs, ATC will include the following:

- a. the name of the SID;
- b. the SID termination fix, if appropriate;
- c. the transition, if necessary; and
- d. the time or location for the aircraft to expect a climb to an operationally suitable altitude or flight level, if necessary.

NOTE: An "expect further clearance" statement may be included in the SID chart.

EXAMPLE: CLEARED TO THE CALGARY AIRPORT, TORONTO ONE DEPARTURE, FLIGHT PLANNED ROUTE.

NOTE: A SID termination fix may be a navaid, intersection or DME and is normally located on an established airway where the SID terminates and the enroute phase of flight commences.

The SID, as published, contains an altitude to maintain after departure; however, ATC may assign an altitude different than the altitude specified in the SID provided the altitude is stated and a readback is obtained from the pilot prior to departure. In addition, where Vector SIDs are used, ATC may assign a different initial departure heading. However, an ATC revision to any item of a SID does *not* cancel the SID.

EXAMPLE: CLEARED TO THE CALGARY AIRPORT, TORONTO ONE DEPARTURE, FLIGHT PLANNED ROUTE, CLIMB TO AMENDED ALTITUDE, SEVEN THOUSAND . . .

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

If an aircraft is issued a Vector SID, radar vectors will be used, as traffic permits, to provide navigational guidance to the filed/assigned route and over the SID termination fix. However, if the controller or the aircraft will gain an operational advantage, the aircraft may be vectored on a route that will not take the aircraft over the SID termination fix.

In this case, if ATC had previously specified a SID termination fix as the location for the aircraft to expect to climb to an operationally suitable altitude or flight level, the controller shall cancel the SID. If, with the change of clearance, it is not practicable for the controller to assign an operationally suitable altitude or flight level, the controller will specify another location or time to expect higher altitude.

EXAMPLE: SID CANCELLED, VECTORS TO (fix or airway) (heading). EXPECT FLIGHT LEVEL THREE FIVE ZERO AT FOUR FIVE D-M-E WEST OF EDMONTON VORTAC.

It is impossible to precisely define “operationally suitable altitudes” to meet requirements in all circumstances.

The following are considered operationally suitable altitudes or flight levels:

- a. piston aircraft — flight planned altitude or lower; and
- b. other aircraft — flight planned altitude or altitude as near as possible to the flight planned altitude taking into consideration the aircraft’s route of flight. As a guideline, an altitude not more than 4,000 ft below the flight planned flight level in the high level structure will be considered as operationally suitable in most cases.

If it is not practicable for the controller to assign the flight planned altitude and if the pilot has not been informed as to when they may expect a clearance to another altitude, it is the pilot’s responsibility to advise ATC if the currently assigned altitude is not satisfactory to permit the aircraft to proceed to the destination airport should a communications failure occur.

The controller will then be required to issue an appropriate “expect further clearance” statement or issue alternative instructions.

Controllers are required to issue a clearance to the altitude or flight level the pilot was told to expect prior to the time or location specified in an “expect further clearance” statement [see ATC 6.3.2.2 b.2.(c)]. The pilot must ensure that further clearance is received because the “altitude to be expected” included in the clearance is not applicable:

- a. once the aircraft has proceeded beyond the fix specified in the “expect further clearance” statement; or
- b. once the time designated in the “expect further clearance” statement has expired.

SIDs may include specific communications failure procedures. These specific procedures supersede the standard communication failure procedures.

SIDs, as published, will not contravene noise abatement procedures. ATC-assigned vectors will not normally contravene noise abatement procedures; however, for flight safety reasons, ATC may be required to issue a vector contrary to noise abatement requirements.

ATC-assigned vectors shall be followed in a timely manner even if they are in conflict with the published noise abatement procedures.

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

The initial call to Departure Control should contain at least:

- a. the aircraft call sign;
- b. the departure runway;
- c. the present vacating altitude (to the nearest 100 ft increment); and
- d. the assigned (SID) altitude.

EXAMPLE: OTTAWA DEPARTURE, BEECH GOLF ALFA BRAVO TANGO. OFF RUNWAY 25, HEADING 250, LEAVING 1900 FOR 4000.

NOTE: An altitude readout is valid if the readout value does not differ from the aircraft reported altitude by more than 200 ft. Pilot altitude reports should be made to the nearest 100-foot increment.

7.6 NOISE ABATEMENT PROCEDURES — DEPARTURE

7.6.1 General

These airplane operating procedures for the take-off and climb have been developed so as to ensure that the necessary safety of flight operations is maintained while minimizing exposure to noise on the ground. One of the two procedures listed in ATC 7.6.3 should be applied routinely for all take-offs where noise abatement procedures are in effect.

Nothing in these procedures shall prevent the pilot-in-command from exercising his/her authority for the safe operation of the airplane, except that when a climb gradient is published, it must be maintained, or alternate procedures must be adopted.

The procedures herein describe the methods for noise abatement when a noise problem is evident. They can comprise any one or more of the following:

- a. use of noise preferential runways to direct the initial and final flight paths of airplanes away from noise-sensitive areas;
- b. use of noise preferential routes to assist airplanes in avoiding noise-sensitive areas on departure and arrival, including the use of turns to direct airplanes away from noise-sensitive areas located under or adjacent to the usual take-off and approach flight paths; and
- c. use of noise abatement take-off or approach procedures, designed to minimize the overall exposure to noise on the ground and, at the same time, maintain the required levels of flight safety.

7.6.2 Noise Preferential Runways

Preferred runway directions for take-off are designated for noise abatement purposes; the objective being to use, whenever possible, those runways that permit airplanes to avoid noise-sensitive areas during the initial departure and final approach phases of flight.

Noise abatement is not the determining factor in runway designation under the following circumstances:

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

- a. if the runway is not clear and dry, i.e., it is adversely affected by snow, slush, ice, water, mud, rubber, oil or other substances;
- b. when the crosswind component, including gusts, exceeds 25 KIAS; and
- c. when the tailwind component, including gusts, exceeds 5 kt.

NOTE: Although ATS personnel may select a preferential runway in accordance with the foregoing criteria, pilots are not obligated to accept the runway for taking off or landing. It remains the pilot's responsibility to decide if the assigned runway is operationally acceptable.

7.6.3 Noise Abatement Departure Procedures (NADP)

NADPs are designed to minimize the environmental impact of departing aircraft without compromising safety. Typically, operators require two procedures: one to minimize close-in noise (NADP1), the other to minimize noise over a more distant noise-sensitive area (NADP2).

Under the NADP concept, airport operators identify their noise and emission control needs and may identify specific noise-sensitive areas. Aircraft operators choose the departure method that safely meets the airport operator's objectives.

When deciding on a noise abatement strategy, it is important to keep in mind that each procedure minimizes noise in its target area at the expense of relatively increased noise elsewhere. NADP1 reduces noise immediately after take-off, but results in higher downrange noise than NADP2, and vice versa. For each aircraft type, powerplant and set of take-off conditions, there is a distance at which the NADP1 and NADP2 noise contours cross over. The area from the take-off to the cross-over point defines the close-in zone of NADP1, while the area beyond the crossover point is the effective range of NADP2.

When developing a noise abatement strategy, airports and air operators should consider the following:

- a. All necessary obstacle data shall be made available to the operator, and the procedure design gradient shall be observed.
- b. The power or thrust settings specified in the aircraft operating manual are to take account of the need for engine anti-icing when applicable.
- c. Noise abatement procedures shall not be executed below 800 ft AAE.
- d. The level of power or thrust for the flap/slat configuration, after power/thrust reduction, shall not be less than:
 - 1. for airplanes in which de-rated take-off thrust and climb thrust are computed by the flight management system, the computed climb power/thrust; or
 - 2. for other airplanes, normal climb power/thrust.
- e. To minimize the impact on training while maintaining flexibility to address variations in the location of noise-sensitive areas, the operator shall develop no more than two noise abatement procedures for each airplane type. One procedure should provide noise benefits for areas close to the airport, and the other for areas more distant from the airport.

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

- f. Any difference of power/thrust reduction initiation height for noise abatement purposes constitutes a new procedure.
- g. Noise abatement departure shall not invalidate an engine-out departure procedure (EODP).
- h. Where possible, each aircraft type should base its standard departure procedure on the noise abatement strategy that minimizes its overall noise impact.
- i. Operators serving certain noise-sensitive airports may need to follow specific, non-standard departure procedures. Crew training and departure information shall address identification and procedural differences associated with alternate noise abatement procedures.
- j. Where applicable, air traffic control agencies should be involved in the development of noise abatement procedures.

In addition to the above general requirements, the following operational limitations apply:

- a. The pilot-in-command has the authority to decide not to execute a noise abatement departure procedure if conditions preclude the safe execution of the procedure.
- b. NADPs requiring reduced take-off power/thrust settings may be flown only when reduced power/thrust is permitted by the aircraft flight manual or aircraft operating manual.
- c. Initial power or thrust reductions shall not be executed below a height of 800 ft AAE.
- d. Aircraft limitations, including maximum body angle limits, shall always be respected.
- e. Noise abatement procedures are not to be used when wind shear warnings exist, or the presence of wind shear or microburst activity is suspected.
- f. Power or thrust settings to be used after the failure or shutdown of an engine or any other apparent loss of performance, at any stage in the take-off or noise abatement climb, are at the discretion of the pilot-in-command, and noise abatement considerations no longer apply. An engine failure during take-off is a non-normal condition, and therefore takes precedence over noise abatement, air traffic, SIDs, departure procedures, and other normal operating considerations.
- g. Conduct of noise abatement procedures is secondary to the satisfaction of obstacle requirements.

NADPs start at or above 800 ft and initiate the final stage at or below 3000 ft AAE, allowing operators to develop specific procedures to suit their local situations.

To illustrate the concept, two NADP-compliant procedures are described below. Each one describes one method, but not the only method, of providing noise reduction for noise-sensitive areas. Operators are free to design other procedures that fit within the NADP envelopes.

7.6.3.1 *NADP 1 (Criteria for a Close-in Noise-sensitive Area) Description*

This procedure involves a power reduction at or above the prescribed minimum altitude (no less than 800 ft) AAE and delaying flap/slat retraction until the prescribed maximum altitude (3000 ft) AAE is attained. At 3000 ft AAE, accelerate and retract flaps/slats on schedule, while maintaining

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

a positive rate of climb, and complete the transition to normal enroute climb speed. The initial climbing speed to the noise abatement initiation point is no less than $V_2 + 10$ kt.

In Summary:

- a. Initial climb to at least 800 ft AAE:
 1. power/thrust as set for take-off;
 2. flaps/slats in take-off configuration; and
 3. climb speed not less than $V_2 + 10$ kt.
- b. At or above 800 ft AAE:
 1. initiate power/thrust reduction;
 2. maintain climb speed not less than $V_2 + 10$ kt to 20 kt; and
 3. maintain flaps/slats in take-off configuration.
- c. At 3000 ft AAE:
 1. maintain positive rate of climb;
 2. accelerate to enroute climb speed; and
 3. retract flaps/slats on schedule.

Specific example of an NADP1 profile:

CA 7
INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

Noise Abatement Take-off Climb — Example of a Procedure Alleviating Noise Close to the Airport (NADP 1)

NOTE: To assist in planning departure spacing, pilots intending to use NADP1 at Canadian airports are to notify ATC Clearance Delivery or Ground Control. At airports where NADP1 is the only procedure to follow, ATC does not need to be notified.

7.6.3.2 NADP 2 (Criteria for a More Distant Noise-sensitive Area) Description

This procedure involves the initiation of flap/slat retraction and accelerating towards V_{ZF} at or above the prescribed minimum altitude (800 ft) AAE but before reaching the prescribed maximum altitude (3000 ft) AAE. The flaps/slats are to be retracted on schedule, while maintaining a positive rate of climb. Intermediate flap retraction, if required for performance, may be accomplished below the prescribed minimum altitude. The power/thrust reduction is initiated at a point along the acceleration segment that ensures satisfactory acceleration performance. At the prescribed maximum altitude, complete the transition to normal enroute climb procedures. The initial climbing speed to the noise abatement initiation point is no less than $V_2 + 10$ kt and the noise abatement procedure is not to be initiated at less than 800 ft AAE.

In summary:

- a. Initial climb to at least 800 ft AAE:
 1. power/thrust as set for take-off;
 2. flaps/slats in take-off configuration; and

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

3. climb speed not less than $V_2 + 10$ kt.
- b. At or above 800 ft AAE, maintain a positive rate of climb and accelerate towards V_{ZF} , and:
 1. retract flaps/slats on schedule; and
 2. reduce power/thrust at a point along the acceleration segment that ensures satisfactory acceleration performance.
- c. Continue the climb to 3000 ft AAE at a climb speed of not less than V_{ZF} .
- d. At 3000 ft AAE, transition to normal enroute climb speed.

Specific example of an NADP2 profile:

Noise Abatement Take-off Climb — Example of a Procedure Alleviating Noise Distant from the Airport (NADP 2)

The use of this guidance material should be limited to acquiring general insight into NADPs. In applying this guidance, users should seek expert noise and emissions advice.

7.7 OBSTACLE AND TERRAIN CLEARANCE

Airports that have an instrument approach procedure (IAP) published also have an instrument flight rules (IFR) departure procedure.

CA 7
INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

There are two types of IFR departure procedures: the standard instrument departure (SID) and the obstacle departure procedure (ODP). SIDs are developed to establish a traffic flow (see paragraph 7.5 — Standard Instrument Departure (SIDs)) while ODPs are pilot initiated. Both types meet obstacle and terrain clearance requirements.

IFR departure procedures are expressed in the form of take-off minima on an airport chart. These procedures are based on the premise that, on departure, an aircraft will:

- a. cross at least 35 ft above the departure end of the runway;
- b. climb straight ahead to 400 ft above airport elevation (AAE) before turning; and
- c. maintain a climb gradient of at least 200 ft/NM throughout the climb to a minimum IFR altitude for enroute operations.

Climb gradients greater than 200 ft/NM may be published. In this case, the aircraft is expected to achieve and maintain the published gradient to the specified altitude or fix, then continue climbing at a minimum of 200 ft/NM until reaching a minimum IFR altitude for enroute operations.

For flight planning purposes, IFR departure procedures assume normal aircraft performance in all cases.

ODPs in the take-off minima box are shown as either:

- a. 1/2 — This indicates that IFR departures from the specified runway(s) will be assured of obstacle and terrain clearance in any direction, if the aircraft meets the previously stated premise. Pilots may consider this procedure as “take-off, climb on course.” The minimum visibility (unless otherwise approved by the appropriate authority) for take-off in these circumstances is 1/2 SM. IFR take-offs for rotorcraft are permitted when the take-off visibility is half the published value, but not less than 1/4 SM.
- b. * (asterisk) — The asterisk (*) following all or specific runways refers the pilot to the applicable minimum take-off visibility (1/2 or SPEC VIS) and the corresponding procedures which, if followed, will ensure obstacle and terrain clearance. Procedures may include specific climb gradients, routings, visual climb requirements, locations of close-in obstacles (see paragraph 7.7.2), or combinations thereof. Where a visual climb is stated in the departure procedure, pilots are expected to comply with the specified take-off minimum visibility (SPEC VIS) corresponding to the appropriate aircraft category listed in the following table:

AIRCRAFT CATEGORY	A	B	C	D
Specified Take-off Minimum Visibility (SPEC VIS) in SM	1	1 1/2	2	2

NOTE: No reductions in SPEC VIS are permitted for rotorcraft. For further information on SPEC VIS, see paragraph 7.7.1.

- c. NOT ASSESSED — IFR departures have not been assessed for obstacles. Pilots-in-command (PICs) are responsible for determining minimum climb gradients and/or routings for obstacle and terrain avoidance.

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

In absence of a published visibility for a particular runway, a pilot may depart IFR only if take-off visibility will allow avoidance of obstacles and terrain on departure. In no case should the take-off visibility be less than 1/2 SM (1/4 SM for rotorcraft).

Where aircraft limitations or other factors preclude the pilot from following the published procedure, it is the PIC's responsibility to determine alternative procedures which will take into account obstacle and terrain avoidance.

Air traffic control (ATC) terms such as "on departure, right turn climb on course" or "on departure, left turn on course" are not to be considered specific departure instructions. It remains the pilot's responsibility to ensure that terrain and obstacle clearance has been achieved by conforming with the IFR departure procedures.

7.7.1 VCOA

The visual climb over the airport (VCOA) — sometimes referred to as "climb visual" or "visual climb" in the Canada Air Pilot (CAP) — was developed to provide an alternate IFR departure procedure for aircraft that cannot meet the greater-than-standard climb gradient specified in the primary instrument departure procedure.

NOTE: Occasionally, VCOA may be the only available departure procedure developed for an airport.

VCOA differs from other instrument departure procedures in that the pilot must maintain certain visual references with the ground and obstacles until reaching a given altitude over the airport.

NOTE: Even though the aircraft is being operated with visual references to the ground, it is still departing on an IFR clearance.

The VCOA text includes a SPEC VIS and a climb-to altitude in feet above sea level. The SPEC VIS is the minimum visibility in statute miles that a pilot requires to maneuver the aircraft while climbing. The climb-to altitude is the minimum altitude above the airport that the aircraft must reach before departing enroute.

It is the pilot's responsibility to see and avoid obstacles while climbing visually. The pilot should be familiar with the local terrain and the obstacles that surround the airport and plan the climb appropriately. Taking local traffic and obstacles into consideration, it is advisable that the pilot keep the airport in sight while climbing. The visual climb segment ends when the aircraft crosses the airport at or above the required minimum altitude. From this point on, obstacles will be cleared if the aircraft maintains a minimum climb gradient of 200 ft/NM to the enroute structure.

The PIC should ensure that the reported ceiling is above the climb-to altitude and that the local prevailing visibility is equal to or greater than that required in the procedure. Additionally, before taxiing for departure, the PIC should inform ATC of the intention to perform a VCOA so that the appropriate coordination can be ensured. If ATC services are not available, then intentions should be broadcast on the ATF (see paragraph 7.9).

7.7.2 Low, Close-In Obstacles

Obstacles that penetrate the standard OCS require the publication of a climb gradient. However, certain close-in obstacles may be exempt from this requirement. Instead, a note is published on

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

the departure procedure and/or on the airport chart. The note alerts the pilot to the nature of the close-in obstacle and gives its height and location so that it may be avoided. An obstacle is determined to be "close-in" if it is within 1 NM of the departure end of the runway, or within 1 NM from the end of the clearway, if a clearway exists. Either way, the charted distance to the obstacle will be noted as being from the departure end of the runway.

If the obstacle(s) cannot be visually acquired during departure, pre-flight planning should take into account the turns or other maneuvers that may be necessary immediately after take-off to avoid the obstacle(s). These obstacles are especially critical to aircraft that do not lift off until close to the departure end of the runway or that climb at the minimum rate.

7.8 RELEASE FROM TOWER FREQUENCY

If the departure airport is located within a terminal control area, the departing IFR flight will be cleared by the tower to contact a specific control unit on a specified frequency once clear of conflicting airport traffic. At certain locations, flights will be advised prior to take-off to change to a specified departure frequency. In this case, the change should be made as soon as practicable after take-off.

If the departure airport is not located within a terminal control area, the pilot, when requesting release from tower frequency, should advise the tower of the agency or frequency to which he/she will change unless directions for the change were included in the ATC clearance.

7.9 IFR DEPARTURES FROM UNCONTROLLED AIRPORTS

Where a pilot-in-command intends to take-off from an uncontrolled airport, the pilot shall:

- a. obtain an ATC clearance if in controlled airspace;
- b. report their departure procedure and intentions on the appropriate frequency before moving on to the runway or before aligning the aircraft on the take-off path; and
- c. ascertain by radio on the appropriate frequency and by visual observation that no other aircraft or vehicle is likely to come into conflict with the aircraft during take-off.

The pilot-in-command shall maintain a listening watch:

- a. during take-off from an uncontrolled airport; and
- b. after take-off from an uncontrolled airport for which an MF has been designated, until the aircraft is beyond the distance or above the altitude associated with that frequency.

As soon as possible after reaching the distance or altitude associated with the MF, the pilot-in-command shall communicate with the appropriate ATC unit or a ground station on the appropriate enroute frequency.

Where IFR departures are required to contact an IFR control unit or ground station after take-off, it is recommended that, if the aircraft is equipped with two radios, the pilot should also monitor the MF during the departure.

If the airport is located in uncontrolled airspace, these procedures shall be followed except that an ATC clearance is not required. In addition to maintaining a listening watch, it is recommended that

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

the pilot-in-command communicate with the appropriate ATC unit, FIC, or other ground station on the appropriate enroute frequency.

NOTE: It is recommended that pilots inform ATC if a flight will not commence within 60 minutes of the proposed departure time stipulated in an IFR flight plan. Failure to do so may result in activating the Search and Rescue (SAR) process.

At an uncontrolled airport, the initial IFR clearance may contain a time or an event-based departure restriction or clearance cancellation.

Examples:

ATC CLEARs AIRLINE123 (IFR clearance) DO NOT DEPART UNTIL 1340; CLEARANCE CANCELLED IF NOT AIRBORNE BEFORE 1349.

or

ATC CLEARs AIRLINE123 (IFR clearance) DO NOT DEPART UNTIL CESSNA ABC HAS LANDED; CLEARANCE CANCELLED IF NOT AIRBORNE BEFORE 1349.

In this first example, the clearance is valid the moment the time turns 1340 and, in both examples, the clearance is cancelled the moment the time turns 1349.

7.10 ALERTING SERVICE IFR DEPARTURES FROM UNCONTROLLED AIRPORTS

At locations where communication with ATS is difficult, pilots may elect to depart VFR and obtain their IFR clearance once airborne. In Canada, if IFR clearance is not received prior to departure, SAR alerting service is activated based on the ETD filed in the flight plan. However, if departing from a Canadian airport that underlies airspace delegated to FAA control, then responsibility for SAR alerting service is transferred to the FAA and FAA procedures apply. In such cases, alerting service is not activated until the aircraft contacts ATS for IFR clearance. Therefore, if the aircraft departs before obtaining its IFR clearance, alerting service is not provided until contact is established with ATS.

7.11 AIRPORT COLLABORATIVE DECISION MAKING (A-CDM)

7.11.1 Introduction

Airport Collaborative Decision Making (A-CDM) is a method for improving the predictability of airport operations, resulting in the more efficient use of available resources and a better passenger experience. A-CDM has been in use for some years in various parts of the world and its benefits have been demonstrated.

A-CDM requires the partners involved in the operation of the airport to exchange certain information that meets prescribed levels of quality and timeliness. Furthermore, aircraft operations will be subject to defined A-CDM procedures. Adherence to these procedures is usually mandatory for most aircraft operators, unless a specific exemption applies.

7.11.2 Operational Concept

One of the objectives of Airport Collaborative Decision Making (A-CDM) is to make aircraft turnaround more predictable and create an efficient outbound flow of traffic. This is achieved by

CA 7
INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

requiring a reliable and accurate Target Off-Block Time (TOBT) for each flight. This TOBT is then used to set up an optimal pushback and start-up sequence that considers all applicable constraints, like de-icing and possible air traffic flow management restrictions.

Operators and their designated representatives are responsible for keeping the TOBT up to date by providing updates as necessary. The flight crew is responsible for operating the aircraft, taking the Target Start-Up Approval Time (TSAT) into account. Failure to comply with these responsibilities will usually result in an operational penalty.

More details about a typical A-CDM operation can be found in the *A-CDM Operations Manual — YYZ Edition*, available from the Greater Toronto Airports Authority at <http://torontopearson.com/acdm/>.

7.11.3 Terms

The following terms and abbreviations are generally used with Airport Collaborative Decision Making (A-CDM):

Terms and Abbreviations Used With A-CDM

Term	Definition
Appropriate radio frequency	The radio frequency that a flight crew must use to contact the Apron Management Unit (AMU) or other air traffic services (ATS) unit as part of an A-CDM procedure.
Calculated Take Off Time (CTOT)	The time calculated and issued by the air navigation service provider that indicates when an aircraft should be airborne if it is to meet the constraints arising from the applicable Traffic Management Initiatives (TMIs).
Commercial air transport operation	An aircraft operation involving the transport of passengers, cargo, or mail for remuneration or hire.
Designated representative	A person or organization authorized by an operator to act and perform tasks on its behalf within the constraints of their representation agreement.
Estimated Off-Block Time (EOBT)	The estimated time at which the aircraft will start movement associated with departure. <i>NOTE: This is the time shown in Item 13 of the flight plan.</i>
Flight crew member	A licensed crew member charged with duties essential to the operation of an aircraft during a flight duty period.
Flight plan	Specified information provided to ATS units, relative to an intended flight or portion of a flight of an aircraft.
General Aviation (GA) operation	An aircraft operation other than a commercial air transport operation. GA operations include business aviation (BA) operations.

CA 7
INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

Terms and Abbreviations Used With A-CDM (continued)

Term	Definition
Ground handler	An organization offering the ground handling services that an aircraft needs for the period during which it is on the ground.
HMI	Human-Machine Interface
Minimum Turnaround Time (MTTT)	The minimum amount of time agreed upon with an operator or ground handler for a specified flight or aircraft type.
Operator	The person, organization, or enterprise engaged in or offering to engage in an aircraft operation.
Pilot-in-Command (PIC)	The pilot designated by the operator, or, in the case of GA, the owner, as being in command and charged with the safe conduct of a flight.
Scheduled Off-Block Time (SOBT)	The time that an aircraft is scheduled to depart from its parking position. <i>NOTE: SOBT is the coordinated airport slot.</i>
Target Off-Block Time (TOBT)	The time at which an operator or ground handler estimates that an aircraft will be ready, with all doors closed, the boarding bridge removed, and a pushback vehicle available and ready to start up/push back immediately upon receiving clearance from the AMU. <i>NOTE: TOBT is equivalent to estimated time of departure (ETD) as used by operators and ground handlers.</i>
Target Start-up Approval Time (TSAT)	The time at which an aircraft can expect to receive start-up/pushback approval. The TSAT may be equal to the TOBT.
Target Take Off Time (TTOY)	The time at which an aircraft is expected to be airborne based on its TSAT and on the time it takes to taxi to the assigned runway.

7.11.4 Scope of Applicability

Airport Collaborative Decision Making (A-CDM) procedures are normally mandatory for all flights operated as commercial air transport or general aviation (GA) operations. Depending on the airport, helicopters and flights identified by any one of the following designators in Item 18 of their flight plan, or by any other agreed-upon means that may be applicable, are sometimes exempt from adhering to A-CDM procedures:

CA 7
INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

Operations Exempted From A-CDM Procedures

STS/FFR	Fire fighting
STS/HEAD	Flight with Head of State status
STS/HOSP	Flight on an actual medical mission
STS/ MEDEVAC	Flight operated for life-critical medical emergency evacuation
STS/SAR	Flight engaged in a search and rescue mission
STS/STATE	Flight engaged in military, customs, or police services
STS/FLTCK	Aircraft performing NAVAID flight check

Any exemptions would be granted based on the type of mission an aircraft is engaged in and not on the identity of the operator.

7.11.5 Airport Collaborative Decision Making (A-CDM) Procedures

Airport Collaborative Decision Making (A-CDM) procedures generally fall into the following three categories:

- a. Commercial Air Transport Operations — Procedures for Operators and Handling Agents
- b. Commercial Air Transport Operations — Flight Crew Procedures
- c. General and Business Aviation Operations — Air Operator Procedures

7.11.5.1 *Commercial Air Transport Operations — Procedures for Operators and Handling Agents*

7.11.5.1.1 *REQUIREMENT FOR ALL FLIGHTS TO HAVE A CURRENT TARGET OFF-BLOCK TIME (TOBT)*

The TOBT is used to indicate when the aircraft will be ready to push back and start its engines. The initial TOBT is usually obtained by the A-CDM system from one of the following sources:

- a. Estimated time of departure (ETD) provided by an operator via the appropriate communications channel;
- b. EOBT from the flight plan; or
- c. SOBT from the airport coordinated schedule data held by the GTAA.

7.11.5.1.2 *PREFERRED WAY OF PROVIDING THE TARGET OFF-BLOCK TIME (TOBT)*

Operators are reminded that using the SOBT may result in an inaccurate TOBT. It is therefore highly recommended that they explore options for providing the ETD via the appropriate communications channel. This can normally be done by contacting the Manager of Operations, Airport Flow, who typically serves as the single point of contact for all A-CDM related matters.

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

7.11.5.1.3 ACCESS TO THE TARGET OFF-BLOCK TIME (TOBT)

The TOBT will be shown and accessible via the A-CDM application and the A-CDM HMI (such as a web portal) as soon as it is set in the A-CDM system.

7.11.5.1.4 PRE-DEPARTURE SEQUENCING — TARGET START-UP APPROVAL TIME (TSAT) GENERATION

Based on the TOBT, a TSAT is generated by the A-CDM system for every flight. The TSAT is used to indicate the sequence in which aircraft can expect to receive pushback and start-up approval, ensuring an optimal flow of traffic to the assigned runways. An update to the TOBT will always result in the recalculation of the TSAT. However, this may not always result in a different TSAT or position in the sequence for the flight concerned.

Any applicable constraints, like the CTOT, resulting from TMLs, taxi times, and possible de-icing time are considered in the calculation of the TSAT to ensure that such constraints are always met.

7.11.5.1.5 ACCESS TO THE TARGET START-UP APPROVAL TIME (TSAT)

The TSAT will be shown in the A-CDM system via the A-CDM application and the A-CDM HMI as soon as stand and runway information are both available in the A-CDM system.

7.11.5.1.6 TARGET START-UP APPROVAL TIME (TSAT) SWAPPING

An operator or handling agent (as applicable) may be able to swap the TSATs between flights of its own operator family if a given flight is delayed or if a reduction of the waiting time for a flight is desirable. Eligible flights are identified as such on the A-CDM system HMI.

7.11.5.1.7 THE IMPORTANCE OF UPDATING THE TARGET OFF-BLOCK TIME (TOBT)

Operators and ground handlers (as appropriate) are responsible for updating the TOBT if there is a difference of ± 5 minutes compared to the initial or previously updated TOBT. Failing to update the TOBT will result in a TSAT that is no longer operationally correct, and this, in turn, may cause the flight to be subject to unnecessary delay.

7.11.5.1.8 TARGET OFF-BLOCK TIME (TOBT) UPDATE LIMITATIONS

The TOBT can normally be updated as many times as necessary until 10 minutes prior to the TOBT. Thereafter, only two more updates are possible. Should a third update be necessary, the operator or handling agent will likely need to contact the Manager of Operations, Airport Flow, for further instructions.

7.11.5.1.9 METHODS FOR UPDATING THE TARGET OFF-BLOCK TIME (TOBT)

The TOBT may be updated via any of the available systems providing access to it.

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

7.11.5.2 *Commercial Air Transport Operations — Flight Crew Procedures***7.11.5.2.1 *TARGET OFF-BLOCK TIME (TOBT) AND TARGET START-UP APPROVAL TIME (TSAT) DELIVERY CHANNELS***

Several channels are often provided for the delivery of the TOBT and TSAT to the flight crew. Operators are free to use any available channel. The following channels are examples:

- a. Advanced Visual Docking Guidance System (AVDGS), where available.
- b. Any specific means of communication that may exist between the operator or ground handler and the flight crew. This means of communication may be shared with other operational communications.
- c. An A-CDM web portal.

7.11.5.2.2 *ACCESS TO THE TARGET OFF-BLOCK TIME (TOBT)*

The TOBT will be displayed for the flight crew on all channels as soon as it is set in the A-CDM system.

7.11.5.2.3 *ACCESS TO THE TARGET START-UP APPROVAL TIME (TSAT)*

The TSAT will be displayed for the flight crew on all channels except the AVDGS as soon as it is set in the A-CDM system. It is expected that the TSAT will be displayed for the flight crew on the AVDGS as follows:

- a. 10 minutes before TOBT; or
- b. 20 minutes before TOBT if the TSAT is later than the TOBT by 20 minutes or more (as may be the case due to TMLs).

7.11.5.2.4 *INFORMATION RELATED TO AIRPORT COLLABORATIVE DECISION MAKING (A-CDM) ON THE ADVANCED VISUAL DOCKING GUIDANCE SYSTEM (AVDGS)*

The information displayed on the AVDGS depends on the operating mode of the A-CDM system, such as:

- a. Traditional Ramp Information Display (e.g. ETD) = A-CDM is not running or A-CDM procedures have been suspended; or
- b. TOBT + time or TOBT + time and TSAT + time = A-CDM is running.

7.11.5.2.5 *CALL READY PROCEDURE*

The flight crew usually must call the Apron Coordinator on the published radio frequency for the airport at TOBT $\pm$ 5 minutes to confirm that the flight is ready as defined for the TOBT and state the location "gate." Thereafter, the crew will need to change to the appropriate radio frequency and monitor it for pushback and start-up approval.

If the flight crew fails to call within the specified time window, it will be assumed that the TOBT is no longer valid and the corresponding TSAT will be removed from the sequence. The operator or

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

ground handler will need to provide a new TOBT for a new TSAT to be generated. This may result in a substantial delay for the flight concerned.

7.11.5.2.6 *PROCEDURES FOR EXTENDED TIMES BETWEEN TARGET OFF-BLOCK TIME (TOBT) AND TARGET START-UP APPROVAL TIME (TSAT)*

The time difference between the TOBT and the TSAT assigned to the flight may be substantial. Airports usually have a policy for aircraft to stay at the gate until the assigned TSAT time. In cases where the gate is required for another flight, or on the specific request of the operator or ground handler, the aircraft concerned could be relocated to a waiting area.

7.11.5.2.7 *AIRPORT COLLABORATIVE DECISION MAKING (A-CDM) — IMPOSED WAITING TIME AND ON-TIME PERFORMANCE*

Traditionally, on-time performance (OTP) is measured by the point in time when the aircraft releases the brakes and is ready for movement associated with departure. If an aircraft waits at the stand for its TSAT, the time between TOBT and TSAT might be counted as a departure delay, adversely impacting the air operator's OTP. It is recommended that air operators implement procedures whereby the time at which the flight crew makes the ready call is considered as the reference for OTP and any waiting time after the TOBT is met can be successfully ignored.

7.11.5.2.8 *PUSHBACK/START-UP APPROVAL*

Depending on the airport, flight crews might expect pushback instructions and start-up approval to be issued on the appropriate radio frequency by the AMU at TSAT $\pm$ 5 minutes without a need for the flight crew to make an additional call.

If the pushback and start-up process does not commence within 2 minutes of the time the approval was issued, the flight crew must call the AMU on the appropriate radio frequency, explain the situation, and request guidance on how to proceed. If this call is omitted, it will be assumed that the TSAT is no longer valid, and it will be removed from the sequence. The operator or ground handler will need to provide a new TOBT for a new TSAT to be generated. This may result in a substantial delay for the flight concerned.

If the pushback and start-up process is interrupted for any reason after the aircraft has cleared the stand area or if the start-up process is expected to take longer than normal, the flight crew must call the AMU on the appropriate radio frequency, explain the situation, and request guidance on how to proceed.

Flight crews are reminded that the actual order of pushback and start-up approval depends on the operational decisions of the AMU and hence, a difference may exist between the system-generated sequence and the sequence as established by the AMU. However, even after a manual intervention, any applicable constraints, like CTOT, would be met by the modified sequence.

7.11.5.2.9 *FLIGHT CREW CONCERNS ABOUT MEETING CONSTRAINTS*

All functions of an A-CDM system are designed to ensure that applicable constraints, most importantly those resulting from TMIs, are always fully met. For example, the TSAT is calculated taking

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

all applicable constraints into account, and if duly observed by the flight crew, the runway slot (CTOT) allocated to the flight will not be missed.

Nevertheless, if flight crew members estimate that a TSAT assigned to them and their applicable CTOT are not compatible, they should contact their operator or ground handler to resolve the issue via the Manager of Operations, Airport Flow.

7.11.5.2.10 *DE-ICING OPERATIONS*

The need for de-icing has a substantial impact on standard A-CDM procedures, in particular the extended taxi times needed to account for the duration of the de-icing operation. To ensure that the de-icing needs of individual flights are properly considered, the following additional procedures are typically applicable during de-icing operations:

- a. A request for de-icing would normally be transmitted by the flight crew on the clearance delivery frequency.
- b. If the flight crew determines, following clearance delivery, that de-icing is required, they would contact the AMU on the applicable radio frequency and request de-icing.

7.11.5.3 *General and Business Aviation Operations — Air Operator Procedures*

7.11.5.3.1 *PRIOR PERMISSION TO OPERATE REQUIRED (RESERVATION)*

Operators or the designated representatives of general and business aviation aircraft typically obtain prior permission to operate (reservation) from the applicable airport authority using A-CDM procedures up to 72 hours before the EOBT, or a minimum of 60 minutes before the EOBT of the planned operation. Some airports have special arrangements with GA/BA Tenant Carriers allowing them to book up to 30 days prior to the EOBT.

Permission or reservation can normally be obtained by contacting the airport authority.

7.11.5.3.2 *REQUIREMENT TO PROVIDE THE TARGET OFF-BLOCK TIME (TOBT)*

Similar to Commercial Air Transport Operations, General and Business Aviation flights must also have a TOBT. Operators can typically obtain their TOBT using the airport's A-CDM web portal.

7.11.5.3.3 *PRE-DEPARTURE SEQUENCING — TARGET START-UP APPROVAL TIME (TSAT) GENERATION*

Based on the TOBT, a TSAT is generated by the A-CDM system for every flight. The TSAT is used to indicate the sequence in which aircraft can expect to receive start-up approval, ensuring an optimal flow of traffic to the assigned runways. An update to the TOBT will always result in the recalculation of the TSAT; however, this may not always result in a different position in the sequence for the flight concerned.

Any applicable constraints, like the CTOT resulting from TMIs, taxi times, and possible de-icing time are considered in the calculation of the TSAT, ensuring that such constraints are always met.

7.11.5.3.4 *ACCESS TO THE TARGET START-UP APPROVAL TIME (TSAT)*

The TSAT will be shown in the A-CDM web portal as follows:

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

- a. 10 minutes before the TOBT; or
- b. 20 minutes before the TOBT if the TSAT is later than the TOBT by 20 minutes or more (as may be the case due to TMIs).

7.11.5.3.5 *THE IMPORTANCE OF UPDATING THE TARGET OFF-BLOCK TIME (TOBT)*

Operators or their designated representatives are obliged to update the TOBT if there is a difference of ± 5 minutes compared to the initial or previously updated TOBT. Failing to update the TOBT will result in a TSAT that is no longer operationally correct. This, in turn, may cause the flight to be subject to unnecessary delay.

7.11.5.3.6 *TARGET OFF-BLOCK TIME (TOBT) UPDATE LIMITATIONS*

The TOBT may normally be updated as many times as necessary until 10 minutes prior to the TOBT. Thereafter, only two more updates are usually possible. Should a third update be necessary, the operator or its designated representative should contact the Manager of Operations, Airport Flow, for further instructions.

7.11.5.3.7 *METHOD FOR UPDATING THE TARGET OFF-BLOCK TIME (TOBT)*

The TOBT must be updated either by updating the flight plan EOBT or via the airports A-CDM web portal.

7.11.5.3.8 *TARGET OFF-BLOCK TIME (TOBT) AND TARGET START-UP APPROVAL TIME (TSAT) DELIVERY CHANNELS*

Several channels are provided for the delivery of the TOBT and TSAT to the flight crew, such as:

- a. The A-CDM web portal;
- b. Any specific means of communication that may exist between the operator or its designated representative and the flight crew; or
- c. The AVGDS, where available.

7.11.5.3.9 *ACCESS TO THE TARGET OFF-BLOCK TIME (TOBT)*

The TOBT will be displayed for the flight crew on all channels as soon as it is set in the A-CDM system.

7.11.5.3.10 *ACCESS TO THE TARGET START-UP APPROVAL TIME (TSAT)*

The TSAT will usually be displayed for the flight crew on all channels as follows:

- a. 10 minutes before the TBOT; or
- b. 20 minutes before the TOBT if the TSAT is later than the TOBT by 20 minutes or more (as may be the case due to TMIs).

7.11.5.3.11 *CALL READY PROCEDURE*

The flight crew should expect to call the AMU Apron Coordinator at TOBT ± 5 minutes to confirm that the flight is ready as defined for the TOBT; they must state their location on the airport. The

CA 7

INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES

Apron Coordinator will advise the TSAT and then instruct the flight crew to change to the appropriate radio frequency. If the flight crew fails to call within the specified time window, it will be assumed that the TOBT is no longer valid and the corresponding TSAT will be removed from the sequence. The operator or its designated representative will need to provide a new TOBT for a new TSAT to be generated. This may result in a substantial delay for the flight concerned.

7.11.5.3.12 *START-UP PROCEDURES*

The start-up procedure typically commences at TSAT $\pm$ 5 minutes without a need for the flight crew to make an additional call.

If the start-up process does not commence within 2 minutes of the TSAT time that was issued, the flight crew must call the AMU on the appropriate radio frequency, explain the situation, and request guidance on how to proceed. If this call is omitted, it will be assumed that the TSAT is no longer valid and it will be removed from the sequence. The operator or its designated representative needs to provide a new TOBT via the A-CDM web portal or via the Manager of Operations, Airport Flow, for a new TSAT to be generated. This may result in a substantial delay for the flight concerned.

If the start-up process is interrupted for any reason or if the start-up process is expected to take longer than normal, the flight crew must call the AMU on the appropriate radio frequency, explain the situation, and request guidance on how to proceed.

Flight crew are reminded that the actual order of start-up approval depends on the operational decisions of the AMU. Hence, a difference may exist between the system-generated sequence and the sequence as established by the AMU. However, even after such manual intervention, the applicable constraints, like CTOT, would be met by the modified sequence.

7.11.5.3.13 *FLIGHT CREW CONCERNS ABOUT MEETING CONSTRAINTS*

All functions of the A-CDM system are designed to ensure that applicable constraints, most importantly those resulting from TMLs, are always fully met. For example, the TSAT is calculated to take all applicable constraints into account. If duly observed by the flight crew, the runway slot (CTOT) allocated to the flight would not be missed.

Nevertheless, if flight crew members estimate that a TSAT assigned to them and their applicable CTOT are not compatible, they should contact their operator or ground handler to resolve the issue via the Manager of Operations, Airport Flow.

7.11.5.3.14 *DE-ICING OPERATIONS*

The need for de-icing has a substantial impact on standard A-CDM procedures, especially the extended taxi times needed to account for the duration of the de-icing operation. To ensure that the de-icing needs of individual flights are properly considered, the following additional procedures are applicable during de-icing operations:

- a. A request for de-icing would normally be transmitted by the flight crew on the airport clearance delivery frequency.
- b. If members of the flight crew determine after clearance delivery that de-icing is required, they must contact the AMU and request de-icing.

CA 7**INSTRUMENT FLIGHT RULES -- DEPARTURE PROCEDURES****7.11.6 Contingency Operations**

If the Airport Collaborative Decision Making (A-CDM) system fails or becomes unreliable, the A-CDM procedures will be suspended. The suspension and eventual restarting of the procedures will be announced via the airport terminal information service (ATIS) broadcast and a NOTAM. During suspension of the A-CDM procedures, no target off-block time (TOBT) or target start-up approval time (TSAT) will be provided.

CA 8

INSTRUMENT FLIGHT RULES - ENROUTE PROCEDURES

SECTION 8

8.1 POSITION REPORTS

Pilots of instrument flight rules (IFR) and controlled VFR (CVFR) flights are required to make position reports over compulsory reporting points shown on the Jeppesen Enroute Charts, and over any other reporting points specified by air traffic control (ATC).

As specified in *Canadian Aviation Regulation* (CAR) 602.125, the position report shall include the information in the sequence set out as follows:

- a. identification;
- b. position;
- c. time over the reporting point in coordinated universal time (UTC);
- d. altitude or flight level;
- e. type of flight plan or flight itinerary filed;
- f. the name of the next designated reporting point and estimated time of arrival (ETA) over that point in UTC;
- g. the name only of the next reporting point along the route of flight (see NOTE); and
- h. any additional information requested by ATC or deemed necessary by the pilot.

NOTE: Reporting points are indicated by a symbol on the appropriate charts. The “designated compulsory” reporting point is a solid triangle and the “on request” reporting point symbol is an open triangle. Position reports over an “on request” reporting point are only necessary when requested by ATC. Therefore, no mention of an “on request” reporting point needs to be made in any position report unless it has been requested by ATC.

Enroute IFR and CVFR flights should establish direct controller-pilot communications (DCPC) wherever possible. Peripheral stations (PAL) have been established at a number of locations to extend the communications coverage. Some PAL locations also employ a radio retransmit unit (RRTU). The purpose of the RRTU is to transmit a pilot's broadcast from one PAL location over another frequency at a different PAL location. This allows the pilot to know when the controller is working communications traffic on a different PAL frequency. Controllers at an area control center (ACC) can disable this equipment when necessary due to the communications workload. However, it must be remembered that, while DCPC provides direct contact with the IFR unit at locations where there is no VFR control and airport advisory service (AAS) or remote airport advisory service (RAAS) is provided, pilots must also communicate with the flight service station (FSS) or flight information center (FIC) for local traffic information. Whenever DCPC cannot be established, or whenever ATC has instructed a pilot to contact an FIC, position reports shall be made through the assigned FIC or the nearest communications agency enroute.

When the pilot-in-command of an IFR aircraft is informed that the aircraft has been IDENTIFIED, position reports over compulsory reporting points are no longer required. Pilots will be informed when to resume normal position reporting.

CA 8

INSTRUMENT FLIGHT RULES - ENROUTE PROCEDURES

In order that flight information and alerting service may be provided to all IFR flights outside controlled airspace, pilots should make position reports over all navigation aids (NAVAID) along the route of flight to the nearest station with air-to-ground communications capability.

If the time estimate for the next applicable reporting point differs from the previously reported estimate by 3 min or more, a revised estimate time should be reported to the appropriate air traffic service (ATS) unit as soon as possible.

8.2 AIRCRAFT COMMUNICATIONS ADDRESSING AND REPORTING SYSTEM (ACARS) AND FUTURE AIR NAVIGATION SYSTEMS (FANS) 1/A

Many aircraft data link applications transfer data using the aircraft communications addressing and reporting system (ACARS). In the early 1990s, air traffic control (ATC) units in the United States began to use ACARS-based predeparture clearance (PDC) applications to alleviate the problem of congestion on clearance delivery frequencies.

Seeing the benefits of this early type of application, airlines began to push for additional air traffic service (ATS) data link applications. Notwithstanding the reduced performance of ACARS networks that existed at the time, using ACARS-based applications was a valuable step towards early introduction of future air navigation systems (FANS). Based on this, various ATS applications operating on the ACARS network were developed. The original Boeing version of these applications was known as FANS 1, whereas the Airbus version was termed FANS A. Today, new FANS applications such as FANS 1/A+ and FANS B continue to be used in airspace not suited for traditional surveillance coverage.

8.3 MACH NUMBER/TRUE AIRSPEED — CLEARANCES AND REPORTS

8.3.1 Mach Number

Clearances to turbojet aircraft equipped with a Machmeter may include an appropriate Mach number. If the Mach number cannot be adhered to, ATC is to be so informed when the clearance is issued. Once accepted, the Mach number shall be adhered to within .01 Mach, unless ATC approval is obtained to make a change. If an immediate temporary change in Mach number is necessary (e.g., because of turbulence), ATC must be notified as soon as possible. When a Mach number is included in a clearance, the flight concerned should transmit its current Mach number with each position report.

8.3.2 True Airspeed (TAS)

ATC is to be notified as soon as practicable of an intended change to the TAS at the cruising altitude or flight level, where the change intended is 5% or more of the TAS specified in the IFR flight plan or flight itinerary.

8.4 ALTITUDE REPORTS

Although the CARs do not specifically direct pilots to report altitude information to ATC, pilots, if not operating in radar airspace (i.e. radar-identified by ATC), should report reaching the altitude to which the flight has been initially cleared. When climbing or descending enroute, pilots shall report when leaving a previously assigned altitude and when reaching the assigned altitude.

CA 8

INSTRUMENT FLIGHT RULES - ENROUTE PROCEDURES

On initial contact with ATC or when changing from one ATC frequency to another, when operating in radar or non-radar airspace, pilots of IFR and controlled VFR flights shall state the assigned cruising altitude and, when applicable, the altitude through which the aircraft is climbing or descending.

In order for ATC to use Mode C altitude information for separation purposes, the aircraft Mode C altitude readout must be verified. The Mode C altitude is considered valid if the readout value does not differ from the aircraft reported altitude by more than 200 ft. The readout is considered invalid if the difference is 300 ft or more. Therefore, it is expected that pilot altitude reports, especially during climbs and descents, will be made to the nearest 100 ft increment.

EXAMPLE: EDMONTON CENTER AIR CANADA 801 HEAVY, LEAVING 8300 FEET, CLIMBING TO FLIGHT LEVEL 350.

If the phrase “report reaching”, “report leaving” or “report passing” is used by ATC the pilot shall comply (CAR 602.31 – *Compliance with Air Traffic Control Instructions and Clearances*).

8.5 CLIMB OR DESCENT

8.5.1 General

During any phase of flight, pilots should adhere to the following procedures:

- a. When an altitude clearance is issued, the pilot should begin climb or descent promptly on acknowledgement of the clearance. The climb or descent should be made at an optimum rate consistent with the operating characteristics of the aircraft. If the above is not the case, or if it becomes necessary to stop the climb or descent, the pilot should advise ATC of the interruption or the delay in departing an altitude.
- b. If the phrase “when ready” is used in conjunction with an altitude clearance or instruction, the change of altitude may be initiated whenever the pilot wishes. The climb or descent should be made at an optimum rate consistent with the operating characteristics of the aircraft. When not informed that the aircraft has been IDENTIFIED, pilots are expected to advise ATC when the altitude change is initiated. Compliance with assigned or published altitude crossing restrictions and speeds is mandatory (CAR 602.31), unless specifically cancelled by ATC. (MEAs are not considered restrictions; however, pilots are expected to remain at or above MEAs).

NOTE: When an aircraft reports vacating an altitude, ATC may assign the altitude to another aircraft. Control will be based on the pilot following these procedures and on the normal operating characteristics of the aircraft.

- c. If a descending aircraft must level off at 10,000 ft ASL to comply with CAR 602.32 while cleared to a lower level, the pilot should advise ATC of the interruption to the descent.
- d. ATC may authorize aircraft to employ cruise climb techniques either between two levels or above a specified level. A clearance or instruction to cruise climb authorizes climb at any given rate as well as temporary levelling at intermediate altitudes. Pilots are expected to advise ATC of the altitude they temporary level off at to the nearest 100 ft. Once the aircraft

CA 8

INSTRUMENT FLIGHT RULES - ENROUTE PROCEDURES

has vacated an altitude during a cruise climb, it may not return to that altitude. ATC will use the following phraseology:

CRUISE CLIMB TO (altitude)

or

CLIMB TO (altitude) CRUISE CLIMB BETWEEN (levels) (or ABOVE [level])

8.5.2 Visual Climb and Descent**8.5.2.1 General**

Application of visual climbs and descents in VMC, under certain circumstances, provides both controllers and pilots with an operational advantage in the conduct of safe and orderly flow of air traffic.

8.5.2.2 Visual Separation From Other Aircraft

ATC may authorize the pilot of an IFR aircraft to conduct a visual climb or descent while maintaining visual separation with the appropriate traffic only if a pilot requests it. Controllers will not initiate or suggest a visual climb/descent in this application. During this altitude change in VMC, pilots must provide their own separation, including wake turbulence separation, from all other aircraft. This application may be exercised in both radar and non-radar environments.

IFR separation is required for all altitude changes in Class A and B airspace. Accordingly, visual climbs or descents will not be approved for aircraft operating in these classes of airspace.

8.6 MINIMUM INSTRUMENT FLIGHT RULES (IFR) ALTITUDES

Except when taking off or landing, aircraft in IFR flight shall be operated at least 1000 ft above the highest obstacle within a horizontal radius of 5 NM of the aircraft (CAR 602.124). Exceptions to this are flights within designated mountainous regions, but outside areas for which minimum altitudes for IFR operations have been established (see ATC – AIRSPACE REQUIREMENTS AND PROCEDURES, Mountainous Regions and ATC Figure 2.11 – Air Defense Identification Zone).

NOTE: The established minimum obstruction clearance altitude (MOCA) for IFR operations provides obstacle clearance above the highest obstacle within the following areas:

a. 1000 ft:

- 1. airways and air routes outside of Designated Mountainous Areas;*
- 2. certain airway and air route segments within Designated Mountainous Areas, which are used in the arrival or departure phase of flight;*
- 3. Safe Altitudes 100 NM outside of Designated Mountainous Areas;*
- 4. all Minimum Sector Altitudes (MSA);*
- 5. instrument approach transitions (including DME arcs);*
- 6. radar vectoring areas [except as in c. 3. below]; and*

CA 8
INSTRUMENT FLIGHT RULES - ENROUTE PROCEDURES

7. Area Minimum Altitude (AMA) outside of Designated Mountainous Areas as shown on the Enroute and Terminal Area Charts.

b. 1500 ft:

- 1. airways and air routes within Designated Mountainous Areas 2, 3, and 4; or*
- 2. Safe Altitude 100 NM within Designated Mountainous Areas 2, 3, and 4.*

c. 2000 ft:

- 1. airways and air routes within Designated Mountainous Areas 1 and 5 with the exception of those segments described in a. 1. above;*
- 2. Safe Altitudes 100 NM within all Designated Mountainous Areas 1 and 5;*
- 3. certain radar vectoring areas within Designated Mountainous Areas; and*
- 4. Area Minimum Altitude (AMA) within Designated Mountainous Areas as shown on the Enroute and Terminal Area Charts.*

Minimum Enroute Altitudes (MEAs) have been established for all designated low level airways and air routes in Canada. An MEA is defined as the published altitude ASL between specified fixes on airways or air routes which assures acceptable navigational signal coverage, and which meets IFR obstacle clearance requirements.

The minimum flight plan altitude shall be the nearest altitude or flight level consistent with the direction of flight (CAR 602.34). This altitude should be at or above the MEA. Unless the MEA is one which is consistent with the direction of flight, it is not to be used in the flight plan or flight itinerary.

As different MEAs may be established for adjoining segments of airways or air routes, aircraft are, in all cases, to cross the specified fix at which a change in MEA takes place, at the higher MEA.

To ensure adequate signal coverage, many of the MEAs on low-level airways are established at altitudes which are higher than those required for obstacle clearance. When this occurs, a MOCA is also published to provide the pilot with the minimum IFR altitude for obstacle clearance. A MOCA is defined as the altitude between radio fixes on low-level airways and air routes, which meets the IFR Air routes clearance requirements for the route segment. Where the MOCA is lower than the MEA, the MOCA is published in addition to the MEA on the Enroute Charts. Where the MEA and MOCA are the same, only the MEA is published.

The MOCA, or the MEA when the MOCA is not published, is the lowest altitude for the airway or air route segment at which an IFR flight may be conducted under any circumstances. These altitudes are provided so that pilots will be readily aware of the lowest safe altitude which may be used in an emergency such as a malfunctioning engine or due to icing conditions. Under ICAO standard atmosphere conditions (ISA), they provide a *minimum* of 1000 ft of clearance above all obstacles lying within the lateral limits of all airways and air routes and 1500/2000 ft in designated mountainous regions.

Pressure altimeters are calibrated to indicate true altitude under ISA conditions, and any deviation from ISA will result in an erroneous altimeter reading. When temperatures are extremely cold, true altitudes will be significantly lower than indicated altitudes. Although pilots may fly IFR at the pub-

CA 8

INSTRUMENT FLIGHT RULES - ENROUTE PROCEDURES

lished MEA/MOCA, in the winter, when air temperatures are much lower than ISA, they should operate at altitudes of at least 1000 ft above the MEA/MOCA.

NOTE: When flying at a flight level in an area of low pressure, the true altitude will always be lower than the corresponding flight level. For example, this “pressure error”, in combination with a temperature error, can produce errors of up to 2000 ft while flying in the standard pressure region at FL100. Further, mountain waves in combination with extremely low temperatures may result in an altimeter over-reading by as much as 3000 ft.

8.7 AIR TRAFFIC CONTROL (ATC) ASSIGNMENT OF ALTITUDES

8.7.1 Minimum Instrument Flight Rules (IFR) Altitude

Within controlled airspace, ATC is not permitted to approve or assign any IFR altitude below the minimum IFR altitude. To ATC, the minimum IFR altitude is the lowest IFR altitude established for use in a specific airspace and, depending on the airspace, concerned this may be:

- a. a Minimum Enroute Altitude (MEA);
- b. a Minimum Obstacle Clearance Altitude (MOCA);
- c. a Minimum Sector Altitude (MSA);
- d. a safe altitude within a radius of 100 NM;
- e. an Area Minimum Altitude (AMA); or
- f. a Minimum Vectoring Altitude (MVA).

When a direct route is given, ATC is responsible for obstacle clearance. Provided that the altitude is at or above the minimum IFR altitude for the controlled airspace where the pilot intends to operate, ATC may use “direct” in a route clearance. ATC may clear aircraft that are traversing airways or air routes below the MEA, but not below the applicable minimum IFR altitude.

Within ATS surveillance coverage, it is common for controllers to issue the MVA when issuing direct routes. An MVA can be lower than a published minimum IFR altitude (MSA, MOCA, MEA, or AMA).

All ATC-assigned altitudes provide obstacle clearance.

A controller is not permitted to clear an aircraft flying on an airway at an altitude below the MEA. However, flight below the MEA, but not below the MOCA, may be approved when specifically requested by the pilot in the interest of flight safety (e.g.: icing/turbulence), to conduct a flight check, for MEDEVAC, or when navigating using GNSS.

Navigational signal coverage is not guaranteed below the MEA; when navigating using NAVAIDS, the pilot should ensure that the aircraft is within, and will remain within, the lateral limits of the airway before requesting approval to fly below the MEA. It should also be noted that flight below the MEA does not guarantee the aircraft will remain in controlled airspace.

CA 8

INSTRUMENT FLIGHT RULES - ENROUTE PROCEDURES

8.7.1.1 DME Intersections on a Minimum Enroute Altitude

The purpose of these fixes is to develop an airway segment where lower MEAs may be applied, thus reducing the high descent rates that otherwise are required when on initial approach to destination.

Pilots without DME normally will not be able to use these lower MEAs and may conceivably experience delays in receiving approach and departure clearances due to other traffic operating below the conventional MEA (i.e., the MEA required for non-DME equipped aircraft). However, in a radar environment, the non-DME equipped aircraft may be cleared at the lower MEA where it will be provided with radar service while operating below the conventional MEA.

8.7.2 Altitudes and Direction of Flight

Pilots will normally file flight plans and be assigned altitudes appropriate to the airway, air route or direction of flight. There are exceptions, and the following information is intended to familiarize pilots with the circumstances of those exceptions.

ATC may assign an altitude *not* appropriate to the airway, air route or direction of flight if:

- a. a pilot requests it because of icing, turbulence, or fuel considerations provided:
 1. the pilot informs ATC of the time or location at which an appropriate altitude can be accepted, and
 2. the altitude has been approved by affected units/sectors; or
- b. an aircraft is:
 1. holding, arriving or departing;
 2. conducting a flight inspection of a NAVAID;
 3. operating within an altitude reservation;
 4. engaged in an aerial survey, mapping flight or test flight;
 5. operating on a polar route (See ATC SPECIAL PROCEDURES – Polar Routes); or
- c. no alternative separation minima can be applied provided:
 1. the altitude has been approved by affected units/sectors, and
 2. the aircraft is cleared to an appropriate altitude as soon as possible, or
- d. the airspace is structured for a one-way traffic flow.

NOTE 1: In situation a., the pilot, when able to accept an appropriate altitude, will be requested to advise ATC. In situation c., the aircraft will be recleared to an appropriate altitude as soon as operationally feasible. Due to safety implications, use of altitudes inappropriate for the direction of flight must be limited, and requests must not be made solely for fuel efficiency reasons. Pilots should make requests only to avoid a fuel situation that might cause an otherwise unnecessary refuelling stop short of the flight planned destination. ATC will not ask the pilot to substantiate a request; if ATC is unable to approve the request, the controller will state the reason and request the pilot's intention.

CA 8

INSTRUMENT FLIGHT RULES - ENROUTE PROCEDURES

NOTE 2: In the application of a. or c. in high level radar controlled airspace, aircraft at an altitude not appropriate for the direction of flight will be issued radar vectors or offset tracks to establish the aircraft at least 5 NM from the centerline of an airway or published track displayed on radar.

PHRASEOLOGY:

VECTORS TO (direction) OF (airway, track) TURN (left/right) TO HEADING (degrees).

ADVISE IF ABLE TO PROCEED PARALLEL OFFSET.

PROCEED OFFSET (number) MILES (right/left) OF CENTERLINE (track/route) AT (significant point/time) UNTIL (significant point/time).

CANCEL OFFSET.

8.8 “1000-FT-ON-TOP” IFR FLIGHT

A “1000-ft-on-top” IFR flight may be conducted provided that:

- the flight is made at least 1000 ft above all cloud, haze, smoke, or other formation;
- the flight visibility above the formation is at least 3 miles;
- the top of the formation is well defined;
- the altitude appropriate to the direction of flight is maintained when cruising in level flight;
- the “1000-ft-on-top” flight has been authorized by the appropriate ATC unit; and
- the aircraft will operate within Class B airspace at or below 12,500 ft ASL, Class C, D, or E airspace.

NOTE: ATC does not apply separation to aircraft operating 1000-ft-on-top except in the following conditions:

- at night, separation is applied between an aircraft operating 1000-ft-on-top and other aircraft if any of the aircraft are holding; and*
- between aircraft operating 1000-ft-on-top and an aircraft operating on an altitude reservation approval.*

8.9 CLEARANCES — LEAVING OR ENTERING CONTROLLED AIRSPACE

ATC will use the phrase “while in controlled airspace” in conjunction with altitude if an aircraft will be entering or leaving controlled airspace. In addition, ATC will specify the lateral point and altitude at which an aircraft is to leave or enter controlled airspace if the instruction is required for separation purposes (see NOTE).

EXAMPLE: LEAVE/ENTER CONTROLLED AIRSPACE (number) MILES (direction) OF (fix) AT (altitude).

LEAVE/ENTER CONTROLLED AIRSPACE AT (altitude).

NOTE: The altitude assigned by ATC need only reflect the minimum safe IFR altitude within controlled airspace. A pilot should be alert to the possibility of a higher minimum safe IFR altitude outside of controlled airspace. If uncertain (or unable to determine) when to enter or leave the area

CA 8

INSTRUMENT FLIGHT RULES - ENROUTE PROCEDURES

where the higher minima is applied, a request for clearance to maintain an altitude that will accommodate the higher minimum IFR altitude should be made.

8.10 CLEARANCE LIMIT

The clearance limit, as specified in an ATC clearance, is the point to which an aircraft is cleared. Further clearance is delivered to a flight prior to arrival at the clearance limit. However, occasions may arise when this may not be possible. In the event that further clearance is not received, the pilot is to hold at the clearance limit, maintain the last assigned altitude, and request further clearance. If communication cannot be established with ATC, the pilot should then proceed in accordance with communication failure procedures as described in ATC — Instrument Flight Rules (IFR — General, Two-Way Communications Failure.

The responsibility rests with the pilot to determine whether or not a received clearance can be complied with in the event of a communications failure. Under such circumstances, a clearance may be refused, but such refusal should specify acceptable alternatives.

8.11 CLASS G AIRSPACE — RECOMMENDED OPERATING PROCEDURES — ENROUTE

When aircraft are maneuvering in the vicinity of uncontrolled airports or cruising in Class G airspace, the lack of information on the movements of other aircraft operating in close proximity may occasion a potential hazard to all concerned. To alleviate this situation, all pilots are advised that:

- a. when operating in Class G airspace, they should continuously monitor the frequency 126.7 MHz whenever practicable;
- b. position reports should be made over all nav aids along the route of flight to the nearest station having air-to-ground communications capability. These reports should be made on frequency 126.7 MHz whenever practicable. If it is necessary to use another frequency to establish communications with the ground station, the report should also be broadcast on 126.7 MHz for information of other aircraft in the area. The report should contain present position, track, altitude, altimeter setting in use, next position and ETA;
- c. immediately before changing altitude, commencing an instrument approach or departing IFR, pilots should broadcast their intentions on 126.7 MHz, whenever practicable. Such broadcasts should contain adequate information to enable other pilots to be fully aware of the position and intentions so that they can determine if there will be any conflict with their flight paths;
- d. at airports where an MF has been designated, arriving pilots shall first broadcast their intentions on 126.7 MHz before changing to the MF. If conflicting IFR traffic becomes evident, this change should be delayed until the conflict is resolved. Pilots departing IFR shall broadcast their intentions on 126.7 MHz, in addition to the MF, prior to takeoff; and
- e. the preceding reporting requirements are considered as the minimum necessary. Pilots are encouraged to make additional reports whenever the possibility of conflicting IFR traffic is suspected. An example would be reporting prior to overflying a facility where cross traffic is probable or where there is a published instrument approach procedure.

CA 8**INSTRUMENT FLIGHT RULES - ENROUTE PROCEDURES**

NOTE: There is no frequency comparable to 126.7 MHz for use by aircraft equipped only with UHF; however, pertinent UHF traffic information will be relayed on the MF by the flight service specialist.

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

9 INSTRUMENT FLIGHT RULES — ARRIVAL PROCEDURES**9.1 ATIS BROADCASTS**

If ATIS is available, all pilots should use it to obtain the basic arrival or departure and airport information as soon as it is practicable.

9.2 STANDARD TERMINAL ARRIVAL (STAR), MINIMUM SECTOR ALTITUDE (MSA) AND TERMINAL ARRIVAL AREA (TAA)

The objective of the STAR, the MSA and the TAA depictions is to provide arriving aircraft with a seamless transition from the enroute structure to the terminal environment.

Unlike the MSAs and TAAs, the STARs are developed to simplify clearance procedures at higher density airports and are individually depicted on the Instrument Approach chart. The MSA and TAA depictions are also on the Instrument Approach chart, but are found in the plan view of the associated approach chart.

A STAR requires the pilot to follow a predetermined route, whereas the MSA and the TAA are less prescriptive and simply offer safe altitudes to which the pilot can descend before commencing the approach. Pilots are to review each STAR issued and to follow the procedure as published. If there is any doubt as to what is required, clarification should be obtained from ATC. Pilots are not required to accept a STAR clearance, and, if they are unable to follow it, they should request alternate instructions.

9.2.1 Minimum Sector Altitude (MSA)

The MSA, as depicted on the approach chart, provides a minimum of 1000 ft clearance above all obstacles within a sector of a circle having a radius of at least 25 NM centered on a radio aid to navigation or on a waypoint located near the airport. Where required, the depiction may be divided into several pie-shaped sectors of varying minimum altitudes. Pilots can locate their sector by superimposing their track to the selected NAVAID onto the MSA depiction.

Unlike TAA depictions, MSA depictions do not allow the sectors to be further partitioned into step-down arcs of varying distances.

NOTE: MSAs are not flight-inspected. Therefore, MSAs based on conventional NAVAIDs may not necessarily assure acceptable navigational signal coverage throughout the 25 NM radius area. RNAV approaches may use either an MSA or a TAA depiction. RNAV approaches that use the MSA shall depict the common minimum altitude only.

9.2.2 Terminal Arrival Area (TAA)

TAAs are developed for aircraft equipped with an FMS and/or a GNSS.

When a TAA is published, it replaces the MSA depiction on the approach chart.

The main advantage of the TAA over the MSA is that it can allow step-down arcs, based on RNAV distances, within its divided areas. This allows the aircraft to descend to lower minimum altitudes while still providing a minimum clearance of 1000 ft above all obstacles.

The standard TAA consists of three areas which are defined by the extension of the initial and intermediate approach segments. These are called the straight-in, left-base, and right-base areas.

CA 9 INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

Figure 9.1 — Basic “T” Approach with TAA Depiction
(STRAIGHT-IN AREA)

NOTE: The standard “T” design of the approach courses may be modified by the procedure designer where required by terrain or for ATC considerations. For instance, the “T” design may appear more like a regularly or irregularly shaped “Y”, or may even have one or both outboard IAWP eliminated, resulting in an upside down “L” or an “I” configuration.

Prior to arriving at the TAA boundary, the pilot should determine which area of the TAA the aircraft will enter by selecting the IWP to determine the magnetic bearing TO the waypoint. That bearing should then be compared with the published bearings that define the lateral boundaries of the TAA areas.

CAUTION: When taking such a bearing, using the left or right IAWP (instead of the IWP) may give a false indication of which area the aircraft will enter. This is critical when approaching the TAA near the extended boundary between the left- and right-base areas, especially where these areas contain different minimum altitude requirements.

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

A standard racetrack holding pattern may be provided at the center IWP/IAWP and, if present, may be necessary for course reversal and for altitude adjustment for entry into the procedure. In the latter case, the pattern provides an extended distance for the descent required by the procedure.

9.2.3 Standard Terminal Arrival (STAR)

A STAR is an ATC IFR arrival procedure published on Jeppesen Terminal charts for use by aircraft with the appropriate navigation capabilities and is coded in many GNSS and FMS databases.

STARs provide the following benefits:

- a. *Predictability for flight crews:* As opposed to radar vectors, STARs allow pilots to be aware in advance of arrival routings and plan more optimum descent profiles.
- b. *Facilitation of clearances and radiotelephony exchanges:* Published STARs reduce the need to communicate detailed descent, speed, and track instructions.
- c. *Increased predictability for ATC:* Controllers observe more consistent aircraft track-keeping and turn performance on STARs due to published speed and altitude restrictions.

9.2.3.1 Conventional Standard Terminal Arrival (STAR)

A conventional STAR can be flown using ground-based NAVAIDs and/or charted headings and traditionally ends with ATC providing radar vectors. Pilots who request a conventional STAR are expected to have sufficient navigation equipment to fly the procedure. Canadian conventional STARs are gradually being replaced with PBN STARs.

9.2.3.2 Performance Based Navigation (PBN) Standard Terminal Arrival (STAR)

With the widespread deployment of PBN, even greater benefits are now possible in STAR design. PBN STARs thus permit an increase in flight safety as well as potential fuel savings. When used by qualified aircraft and operators, a PBN STAR can result in greater reliability, repeatability, and predictability of aircraft flight paths.

A PBN STAR is titled “STAR (RNAV)” and is a performance-based operation in which the performance requirements are specified by the publication of a navigation specification (such as RNAV 1 or RNP 1) on the chart in the PBN requirements box. Detailed explanations of navigation specifications can be found in ATC — Airspace Requirements and Procedures — Performance-based Navigation (PBN).

In cases where a navigation specification has not yet been assigned to a PBN STAR, the following equipment would be required:

- a. at least one RNAV system or FMS certified for terminal use that meets either of the following standards:
 - (i) AC 20-130 (or later approved) *Airworthiness Approval of Navigation or Flight Management Systems Integrating Multiple Navigation Sensors*; or

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

- (ii) AC 20-138 (or later approved) *Airworthiness Approval of Global Positioning System (GPS) Navigation Equipment for use as a VFR and IFR Supplemental Navigation System*, and
- (iii) TSO C129a, *Airborne Supplemental Navigation Equipment Using the Global Positioning System GPS*);
- b. at least one automatic radio-updated IRU, if the RNAV system or FMS does not use a GPS sensor;
- c. a current database containing the waypoints, for the STAR to be flown, that can be automatically loaded into the RNAV system or FMS active flight plan;
- d. a system capable of following the RNAV system or FMS lateral flight path and limiting the cross-track error deviation to $\pm \frac{1}{2}$ the navigation accuracy associated with the procedure or route; and
- e. an electronic map display.

9.2.3.3 Flight Planning

Authorized aircraft and air operators who meet the appropriate navigation specification (or the equipment list shown above for STARs without a navigation specification) may file STARs in their flight plan. Operators not authorized to flight plan PBN STARs are expected to file plans that include waypoints from the expected STAR procedure (or plans that are as close to the waypoints as possible), and include the remark in field 18 of the flight plan: RMK/NO RNAV STAR.

When included in a flight plan, the STAR will form part of the flight-planned route in the ATC clearance.

NOTE: Mandatory IFR Routes may include a STAR. See ATC — ATC Special Procedures — Mandatory Instrument Flight Rules (IFR) Routes.

9.2.3.4 Procedure Identification

A STAR can designate multiple lateral routes, dependent on the runway in use, for an aircraft to fly from various points along the enroute phase of flight to the approach phase with little or no ATC intervention. These lateral routes (referred to as transitions) are listed on the STAR chart and may include instructions for management of the vertical profile. The procedure identification on a STAR chart includes the primary procedure identification and the enroute transition identification.

The primary procedure identification consists of the following three elements:

- Procedure type
- Plain-language designator
- Coded designator

The procedure type is shown as one of the following:

- STAR: identifies the procedure as a conventional STAR

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

– STAR (RNAV): identifies the procedure as a PBN STAR

The plain-language designator is the spoken identification for the STAR procedure. It consists of a basic indicator, a validity number, and the term “ARR”. The validity number is a number between one and nine assigned sequentially after a qualifying procedure amendment. Example: UDN0X ONE ARR. A qualifying procedure amendment is a change in a procedure track or another significant change affecting the database coding of the procedure.

When a STAR procedure includes transitions from the enroute airspace structure, the enroute transitions are identified in similar fashion to the main STAR procedure. The enroute transition identification includes a plain-language designator and a coded designator. The plain-language designator is the spoken identification for the enroute transition and, while not always, it is usually derived from the name of the first point of the enroute transition. The coded designator is the database/flight planning identification for the enroute transition and is derived from both the enroute transition plain-language designator and the primary procedure identification. For example, the LETAK TRANSITION (LETAK.IMEBA3) on the IMEBA THREE ARR into CYYZ is highlighted on the chart below.

Figure 9.2 — Example of an Enroute Transition on the IMEBA THREE ARR into CYYZ

9.2.3.5

Altitude Restrictions

Altitude restrictions may be included in the STAR. Although an aircraft is expected to follow the charted lateral track of the cleared STAR without further ATC clearance, as per the flight-planned/cleared route, such is not the case with the STAR vertical profile; ATC has to issue descent clearance, and when a lower altitude is issued, pilots shall descend on the STAR profile to the ATC-

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

assigned altitude. Unless specially cancelled by ATC, all charted restrictions above the assigned altitude on the STAR remain mandatory.

9.2.3.6 *Speed Restrictions*

Pilots must follow charted speed restrictions on a STAR. An ATC-assigned speed restriction supersedes any STAR-charted speed restrictions and must be followed until CAR 602.32 prohibits the pilot from flying at that speed.

9.2.3.7 *Operating Procedures*

When included in a flight plan, the STAR forms part of the flight-planned route received in the initial ATC clearance. When a flight plan that includes a STAR has been filed, or when the pilot receives and acknowledges a clearance that includes a STAR, the pilot is expected to fly the charted lateral track without further clearance. However, descent clearance must be obtained from ATC before commencing the vertical profile.

9.2.3.8 *Top of Descent (TOD)*

Sophisticated FMSs have the ability to determine precisely where to begin a descent from cruise altitude in order to minimize fuel usage, pollution, and noise by having the engines at their minimum thrust setting (idle) from cruise altitude to the final approach fix. This point is known as TOD. The most recent Canadian STAR procedures are carefully designed to allow the greatest benefits from idle descents while meeting the most common ATC requirements.

In order to maintain safety and airspace capacity, ATC may have to issue tactical instructions such as interim altitudes, speed control, radar vectors, or direct routes. Tactical instructions impact the TOD planning carried out by the FMS. For instance, delaying the planned descent, reducing the speed, or shortcutting STAR intermediate waypoints translate into a steeper descent angle, requiring the use of speed brakes and/or a longer flying distance. A premature descent clearance will translate into a shallower descent angle, requiring the use of engine thrust. To help mitigate the impact of these tactical instructions, ATC will endeavour to cancel or assign altitude and speed restrictions as far in advance as possible to help the flight crew re-optimize the descent.

In some terminal areas, the enroute controller may issue initial descent instructions at TOD, but it may be an arrival controller who could ultimately be responsible for sequencing aircraft to the final approach course. Pilots should always state their requested approach when making initial contact with the controller who will be responsible for sequencing the aircraft to the final approach course, even if the initial descent clearance was issued by another controller.

9.2.3.9 *Descent Planning*

Some PBN instrument approach procedures require fewer track miles to be flown, necessitating STAR vertical profiles significantly lower than those required for other approaches.

There are two main classifications of PBN approach procedures:

- Required navigation performance approach (RNP APCH) procedures, bearing the chart title “RNAV (GNSS)”,

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

- Required navigation performance authorization required approach (RNP AR APCH) procedures, bearing the chart title “RNAV (RNP)”.

Altitude constraints specific to RNP AR APCH are built into STAR procedures in order to enhance RNP AR APCH connectivity. While these constraints are a benefit for aircraft planning an RNP AR APCH, they are a drawback for aircraft planning other approach types, as they force them below an optimum vertical profile and may require a longer final approach segment. For maintaining the flight efficiencies of aircraft not planning an RNP AR APCH, some STAR procedures may offer guidance for descent planning.

9.2.3.10 *Closed Standard Terminal Arrival (STAR) Procedures*

A closed STAR procedure provides a continuous path from the enroute structure and automatically joins up with the final approach course. A closed STAR terminates at the FACP. On a closed STAR, when an approach clearance is received, the pilot will continue to comply with all published altitude and speed restrictions, fly the charted track to the FACP, intercept the final approach course, and fly the straight-in approach. A closed STAR procedure is normally used when the inbound track is within plus or minus 90° of the final approach course to the runway.

ATC always strives to issue approach clearances before aircraft reach the end of closed STARs, but in very rare cases (such as a distress call in progress on the frequency, frequency congestion, or high ATC workload), this may not always be possible. In order to assure obstacle clearance throughout the STAR and the approach lateral tracks, if an aircraft were to reach the end of a closed STAR prior to the issuance of an approach clearance, the pilot would be expected to safely intercept the final approach course and fly inbound maintaining the last assigned altitude. In the extremely remote case in which the aircraft reaches the end of the final approach track and further clearance has still not been obtained, the pilot would be expected to track the lateral position of the missed approach procedure for what would have been the anticipated approach, and maintain the last assigned altitude or climb to the anticipated missed approach altitude if the missed approach altitude is higher.

9.2.3.11 *Open Standard Terminal Arrival (STAR) Procedures*

Similar to a closed STAR, an open STAR procedure also provides a continuous path from the enroute structure but does not automatically join up with the final approach course. Open STARs are charted with an expectation of radar vectors and essentially place aircraft in a downwind to simplify approach sequencing. A STAR can be linked to an approach once ATC has issued an approach clearance. Unless ATC issues an approach clearance, aircraft must continue on the STAR procedure while awaiting ATC instructions. Once an approach clearance is issued, the pilot is expected to comply with any remaining STAR charted altitude and speed restrictions, intercept the final approach course using the assigned transition (or the assigned radar vectors), and conduct a straight-in approach. If an approach clearance is not received prior to the transition that is expected by the pilot, the aircraft will maintain the STAR as charted, and ATC will provide vectors to a point from which the aircraft can fly the straight-in approach.

Figure 9.3 — Example of a Closed STAR for Rwy 24L and 24R and an Open STAR for Rwy 06L and 06R

9.2.3.12 *Transitioning from an Open Standard Terminal Arrival (STAR) to an Approach Procedure*

The open STAR procedure normally offers the pilot an option to link the lateral profile of the STAR procedure to the lateral profile of the approach procedure through the use of a variety of approach transitions. A STAR can connect to some ILS approach procedures by using “GNSS REQUIRED” transitions published on the approach procedure. A STAR can connect to some RNP APCH (bearing the chart title “RNAV (GNSS)”) when the approach IAWP is also published on the STAR. Similarly, a STAR can connect to an RNP AR APCH (bearing the chart title “RNAV (RNP)”) when the approach IAWPs are published on the STAR. When a waypoint is published on both a STAR and an approach, it is referred to as a STAR/approach interface waypoint.

NOTE: While it may still exist at a few airports, the connection between STAR DTW and FACF is gradually being phased out.

Approach Clearances

An approach clearance needs to be received prior to commencing an approach procedure; otherwise, aircraft are expected to continue flying the STAR procedure while awaiting further instructions. ATC always strives to provide transitions and early approach clearances, but sometimes traffic conditions necessitate vectors to intercept the final approach course.

Below are examples of typical FMS displays when a STAR/approach interface waypoint is used to link a STAR to an approach, both before and after an approach clearance has been issued. In both examples, before the approach clearance has been received, a discontinuity appears in the FMS waypoint list, since linking the STAR to the approach has not yet been permitted.

Linking the STAR to the approach without ATC clearance could result in a loss of separation.

Figure 9.7 — Open STAR to RNP APPROACH

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

Figure 9.8 — Open STAR to RNP AR APPROACH

Once the aircraft is cleared for an approach with a specified transition, if the FMS does not link the STAR to the approach before the STAR/approach interface waypoint, or if the aircraft is unable to execute the procedure, the pilot must advise ATC immediately upon recognizing the missed transition and wait for alternate instructions.

9.2.3.14 Radar Vectors to Final

Sometimes, depending on traffic and options for ATC to sequence aircraft, the published transition may not be available, and radar vectors will be provided to join the final approach course. If this occurs, and a clearance for the transition is not possible, pilots will not be expected to re-configure for a new transition or for another approach. ATC will state that they are unable to provide a particular transition and that the aircraft should expect radar vectors.

9.2.3.15 Amending Routes

ATC may amend STAR routes by clearing the aircraft direct to a waypoint depicted within the STAR. ATC will confirm what to expect if they intend for the aircraft to rejoin the STAR procedure when initiating radar vectors. When an aircraft is cleared direct to a STAR/approach interface waypoint, unless it is cleared for an approach, the pilot shall proceed direct to the STAR waypoint, and not to the approach waypoint, to re-intercept the STAR profile.

9.2.3.16 Direct Routings to an Initial Approach Waypoint (IAWP)/Intermediate Waypoint (IWP)

An RNP AR APCH (bearing the chart title “RNAV (RNP)”) normally offers RF leg segments to intercept the final approach course. Obstacle protection areas on these RF legs are designed with the consideration that the aircraft be established at the published speed and altitude, on the track centerline, and with the wings level prior to the beginning of the RF leg. The straight segment prior to these RF legs provides adequate time for aircraft to stabilize in this configuration. Direct

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

routings to the beginning of RF leg segments are not permitted. An RNP AR APCH must not begin inside of the IWP.

9.2.3.17 *Canceling Standard Terminal Arrival (STAR) Procedures*

Accepting a visual approach clearance automatically cancels the STAR procedure. A STAR may also be cancelled by ATC if required. If ATC cancels a STAR, the pilot should expect alternate instructions (either radar vectors to the final approach course, or a new route clearance). A STAR that has been cancelled may be reinstated by ATC.

9.3 APPROACH CLEARANCE

When using direct controller pilot communications, ATC normally advises pilots of the ceiling, visibility, wind, runway, altimeter setting, approach aid in use, and pertinent airport conditions (CRFI, RSC, etc.) immediately prior to or shortly after descent clearance. Upon acknowledging receipt of the current ATIS broadcast, the pilot is advised by ATC of the current airport conditions only if they are changing rapidly.

Aircraft destined to airports which underlie controlled low level airspace and for which there is a published instrument approach procedure, will be cleared out of controlled airspace (vertically) via the published instrument approach procedure.

EXAMPLE: ATC CLEARS (aircraft identification) OUT OF CONTROLLED AIRSPACE VIA (name, type) APPROACH.

Aircraft destined to airports which underlie controlled low level airspace and for which there is not a published instrument approach procedure will be cleared to descend out of controlled airspace and informed of the appropriate minimum IFR altitude.

EXAMPLE: ATC CLEARS (aircraft identification) TO DESCEND OUT OF CONTROLLED AIRSPACE VICINITY OF (airport name). THE (minimum IFR altitude) IS (number) FEET.

The pilot may elect to cancel IFR as soon as visual conditions permit the continuation of the flight under VFR, or remain on the IFR flight plan until the aircraft has landed and the pilot files an arrival report. Should the pilot anticipate that visual conditions to permit continued flight under VFR may not be achieved, the pilot may arrange with ATC to have the MEA protected.

Aircraft destined to airports which underlie controlled high level airspace and where there is no minimum IFR altitude established that would prohibit such a maneuver, will be cleared out of controlled high level airspace.

EXAMPLE: ATC CLEARS (aircraft identification) OUT OF (type of airspace).

When an approach clearance is issued, the published name of the approach is used to designate the type of approach if adherence to a particular procedure is required. If visual reference to the ground is established before completion of a specified approach, the aircraft should continue with the entire procedure unless further clearance is obtained.

EXAMPLE: CLEARED TO THE OTTAWA AIRPORT, STRAIGHT-IN ILS RUNWAY ZERO SEVEN APPROACH.

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

EXAMPLE: CLEARED TO THE TORONTO AIRPORT, ILS RUNWAY ZERO SIX LEFT APPROACH.

The number of the runway on which the aircraft will land is included in the approach clearance when a landing will be made on a runway other than that aligned with the instrument approach aid being used.

EXAMPLE: CLEARED TO THE OTTAWA AIRPORT, STRAIGHT-IN ILS RUNWAY ZERO SEVEN APPROACH/CIRCLING PROCEDURE SOUTH FOR RUNWAY THREE TWO.

NOTE: If the pilot begins a missed approach during a circling procedure, the published missed approach procedure as shown for the instrument approach just completed shall be flown. The pilot does not use the procedure for the runway on which the landing was planned.

At some locations during periods of light traffic, controllers may issue clearances that do not specify the type of approach.

EXAMPLE: CLEARED TO THE LETHBRIDGE AIRPORT FOR AN APPROACH.

When such a clearance is issued by ATC and accepted by the pilot, the pilot has the option of conducting any published instrument approach procedure. In addition, the pilot also has the option of proceeding by the route so cleared by ATC in a previous clearance, by any published transition or feeder route associated with the selected procedure, or by a route present position direct to a fix associated with the selected instrument approach procedure. Pilots who choose to proceed to the instrument procedure fix via a route that is off an airway, air route or transition are responsible for maintaining the appropriate obstacle clearance, complying with noise abatement procedures and remaining clear of Class F airspace. As soon as practicable after receipt of this type of clearance, it is the pilot's responsibility to advise ATC of the type of published instrument approach procedure that will be carried out, the landing runway and the intended route to be flown.

This clearance does not constitute authority for the pilot to execute a contact or visual approach. Should the pilot prefer to conduct a visual approach (published or non-published) or a contact approach, the pilot must specifically communicate that request to the controller.

Upon changing to the Tower or FSS frequency, pilots should advise the agency of the intended route and published instrument approach procedure being carried out.

The pilot should not deviate from the stated instrument approach procedure or route without the concurrence of ATC because such an act could cause dangerous conflict with another aircraft or a vehicle on a runway.

A clearance for an approach may not include any intermediate altitude restrictions. The pilot may receive this clearance while the aircraft is still a considerable distance from the airport, in either a radar or non-radar environment. In these cases, the pilot may descend, at his/her convenience, to whichever is the lowest of the following IFR altitudes applicable to the position of the aircraft:

- a. Minimum Enroute Altitude (MEA);
- b. published transition or feeder route altitude;
- c. Minimum Sector Altitude (MSA) specified on the appropriate instrument approach chart;

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

- d. safe altitude 100 NM specified on the appropriate instrument approach chart; or
- e. when in airspace for which the Minister has not specified a higher minimum, an altitude of at least 1000 feet above the highest obstacle within a horizontal radius of 5 NM (1500 feet or 2000 feet within designated mountainous regions depending on the zone) from the established position of the aircraft.

NOTE: When a pilot receives and accepts an ATC clearance which authorizes descent to MSA or a safe altitude 100 NM during normal IFR operations, descent below the MEA for the preceding enroute phase should not commence until the pilot can positively establish the aircraft's position by means of a bearing, radial, DME, radar or visual means.

CAUTION: Pilots are cautioned that descents to MSA or Safe Altitude 100 NM may, under certain conditions, exit controlled airspace. ATC provides IFR separation within controlled airspace only.

9.4 DESCENT OUT OF CONTROLLED AIRSPACE

ATC may not clear an aircraft to operate below the MEA of an airway, nor below the minimum IFR altitude in other controlled low level airspace. The pilot, however, may operate at the MOCA, and ATC will approve flight at the MOCA at the pilot's request. If unable to cancel IFR at the MEA, the pilot may advise that he/she intends to descend to the MOCA. By prior arrangement with ATC, the MEA will be protected in the event the pilot does not encounter visual conditions at the MOCA. Under this arrangement, the MEA will be protected:

- a. until the pilot files an arrival report (see ATC 3.12.1);
- b. for 30 minutes; to allow descent to the MOCA and return to the MEA when communication is restored with ATC; or
- c. if ATC does not hear from the pilot under a. or b. above, until the aircraft is estimated to have arrived at the filed alternate plus 30 minutes.

9.5 ADVANCE NOTICE OF INTENT IN MINIMUM WEATHER CONDITIONS

ATC can handle missed approaches more efficiently if the controller knows the pilot's intentions in advance. They can use the extra time to plan for the possibility of a missed approach and thus provide better service in the event of an actual missed approach.

Pilots should adopt the following procedures as the occasion arises.

On receipt of approach clearance, when the ceiling and visibility reported at the destination airport is such that a missed approach is probable, the pilot should advise the controller as follows:

IN THE EVENT OF MISSED APPROACH REQUEST (altitude or level) VIA (route) TO (airport).

Implementation of this procedure increases the amount of communications, but the increase can be minimized if pilots employ it only when there is a reasonable chance that a missed approach may occur.

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

9.6 CONTACT AND VISUAL APPROACHES**9.6.1 Contact Approach**

A contact approach is an approach wherein an aircraft on an IFR flight plan or flight itinerary, having an ATC clearance, operating clear of clouds with at least 1 NM flight visibility and a reasonable expectation of continuing to the destination airport in those conditions, may deviate from the instrument approach procedure and proceed to the destination airport by visual reference to the surface of the earth. In accordance with CAR 602.124, the aircraft shall be flown at an altitude of at least 1000 feet above the highest obstacle located within a horizontal radius of 5 NM from the estimated position of the aircraft in flight until the required visual reference is acquired in order to conduct a normal landing. Pilots are cautioned that conducting a contact approach in minimum visibility conditions introduces hazards to flight not experienced when flying IFR procedures. Familiarity with the airport environment, including local area obstacles, terrain, noise sensitive areas, Class F airspace and airport layout, is paramount for a successful contact approach in minimum visibility conditions. Pilots are responsible for the adherence to published noise abatement procedures and compliance with any restrictions that may apply to Class F airspace when conducting a contact approach.

NOTE: This type of approach will only be authorized by ATC when:

- a. the pilot requests it; and*
- b. there is an approved functioning instrument approach, a published GNSS approach for the airport.*

An aircraft that requests a contact approach to an airport served only by a GNSS approach is indicating to ATS that the pilot understands that no ground-based approach is available and is confirming that it is able to conduct a GNSS approach.

ATC will ensure IFR separation from other IFR flights and will issue specific missed approach instructions if there is any doubt that a landing will be accomplished. Pilots are cautioned that when any missed approach is initiated while conducting a contact approach, obstacle and terrain avoidance is the pilot's responsibility even though specific missed approach instructions may have been issued by ATC. ATC only ensures appropriate IFR separation from other IFR aircraft during contact approaches.

NOTE: ATC will not issue an IFR approach clearance that includes clearance for a contact approach, unless there is a published and functioning instrument approach procedure (IAP) or a restricted instrument approach procedure (RIAP) authorized by Transport Canada for the airport. Where a GNSS approach is the only available IAP or RIAP, this fulfils the requirement for a "functioning instrument approach."

9.6.2 Visual Approach

A visual approach is an approach wherein an aircraft on an IFR flight plan, operating in VMC under the control of ATC and having ATC authorization, may proceed to the destination airport. It permits aircraft to manage their lateral and vertical flight profiles according to the runway.

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

To gain operational advantages in a surveillance environment, the pilot may request a visual approach, or ATC may initiate one, provided that:

- a. the reported ceiling at the destination airport is 500 ft or more above the minimum IFR altitude and the ground visibility is 3 statute miles or more;
- b. at a controlled or uncontrolled airport, the pilot reports sighting the airport; and
- c. at a controlled airport:
 1. the pilot reports sighting the preceding aircraft and is instructed by ATC to follow that aircraft; or
 2. the pilot reports sighting the airport but not the preceding aircraft, in which case ATC will ensure separation from the preceding aircraft until:
 - (a) the preceding aircraft has landed; or
 - (b) the pilot has sighted the preceding aircraft and been instructed to follow or maintain visual separation from it.

ATC considers acceptance of a visual approach clearance as acknowledgement that the pilot should be responsible for:

- a. maintaining visual separation from the preceding aircraft that the pilot has been instructed to follow;
- b. maintaining adequate wake turbulence separation from the preceding aircraft that the pilot has been instructed to follow;
- c. navigating to the final approach course;
- d. adhering to published noise abatement procedures and avoiding Class F airspace; and
- e. at uncontrolled airports, maintaining appropriate separation from VFR traffic that, in many cases, will not be known to ATC.

ATC will issue a visual approach clearance and, as required, supplement it with additional instructions such as:

1. Heading assignment:
 - To ensure the aircraft stays separated from preceding or succeeding traffic. ATC will consider the aircraft's altitude and remaining distance to the airport when using this method; and
 - To comply with parallel runway operation rules that require a 30 degree intercept heading to final prior to issuing the visual approach clearance.
2. Distance to intercept the final approach course and/or altitude to establish separation from traffic under the control tower's responsibility using references to:
 - published NAVAIDs, fixes, or waypoints;
 - the distance from the runway; and

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

- a prominent landmark on the final approach course.

ATC may anticipate that pilots will navigate to the final approach course using the following methods depending on the aircraft's altitude and distance from the airport:

1. Flying the shortest distance to the airport while complying with ATC and noise abatement restrictions; or
2. Using the on-board navigation guidance to follow a lateral profile reflecting any remaining portion of the STAR and the previously planned published instrument approach procedure. This provides the following benefits:
 - enhanced aircraft energy management;
 - predictability;
 - reduced flight deck workload;
 - flexibility in meeting stabilized approach criteria; and
 - adherence to altitude restrictions during nighttime conditions.

As both methods differ in terms of flying distance, it is good airmanship for pilots to advise ATC of the planned flight path, especially if it is likely to be unexpected or unpredictable, such as cases involving the widening of the base leg or the inability to shorten the flying distance as anticipated by ATC.

9.6.2.1 *Missed Approach*

A visual approach is not an IAP, and except for published visual approach procedures in the CAP, there are no procedures associated with a missed visual approach; visual approaches therefore have no missed approach segment. If a go-around is necessary for any reason, aircraft operating at controlled airports will be issued an appropriate advisory/clearance/instruction by the tower to ensure that separation from other airport traffic is maintained.

NOTE: It is understood that the execution of a missed approach maneuver involves critical internal flight deck communications and high pilot workload. If these instructions are required for planning, pilots may request them before the approach clearance or at any time prior to initiating the missed approach.

ATC instructions will guide the pilot to:

- (i) continue flying the issued IFR clearance; or
- (ii) integrate into the airport VFR circuit.

a. Controlled Airports

At controlled airports, until missed approach instructions are issued, ATC should anticipate that pilots conducting a go-around from a visual approach will:

- (i) initially fly the runway heading;
- (ii) follow the published missed approach instructions for the IAP requested by the pilots and acknowledged by ATC; or

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

(iii) follow the published missed approach instructions for the IAP advertised on the ATIS.

b. Uncontrolled Airports

At uncontrolled airports, aircraft crews are required to remain clear of clouds and are expected to complete a landing as soon as possible. If a landing cannot be accomplished, the aircraft crew is required to:

- (i) remain clear of clouds; and
- (ii) maintain separation from other airport traffic.

The crew is also expected to contact ATC as soon as possible for further clearance.

ATC separation from other IFR aircraft is only assured once further ATC clearance has been received and acknowledged by the aircraft crew.

9.7 RADAR ARRIVALS**9.7.1 General**

Radar separation is applied to arriving aircraft in order to establish and maintain the most desirable arrival sequence to avoid unnecessary “stacking”. In the approach phase, radar vectoring is carried out to establish the aircraft on an approach aid. The initial instruction is normally a turn to a heading for radar vectors to a final approach to the runway in use. Should a communications failure occur after this point, the pilot should continue and carry out a straight-in approach if able, or carry out a procedure turn and land as soon as possible. Aircraft are vectored so as to intercept the final approach course approximately 2 NM from the point at which final descent will begin.

EXAMPLE: JULIETT WHISKEY CHARLIE, TURN LEFT HEADING ONE SEVEN ZERO TO INTERCEPT FINAL APPROACH COURSE. SEVEN MILES FROM AIRPORT. CLEARED FOR STRAIGHT-IN ILS RUNWAY ONE FIVE LEFT APPROACH. CONTACT TORONTO TOWER ON ONE ONE EIGHT DECIMAL SEVEN NOW.

9.7.2 Radar Required

Traditionally, instrument approach procedures have been developed to include a procedure turn initial approach segment. Procedure turns permitted the pilot to “self-navigate” the aircraft within the procedure in order to place the aircraft in a position to conduct a normal landing. Introducing DME and other feeder routes or transitions permitted the pilot to conduct a straight-in procedure without conducting the procedure turn. Most instrument procedures today are accomplished without conducting a procedure turn.

Instrument approaches at Canada’s major airports are conducted by radar vectors to the final approach course. While procedure turns are depicted on the instrument approach procedures at these airports, procedure turns are never flown. ATC route and space all aircraft within the terminal area in order to provide a systematic flow of the air traffic. An aircraft conducting a procedure turn maneuver at these major centers would cause serious traffic disruptions which may lead to losses of separation or possibly a mid-air collision.

Instrument procedures are being introduced eliminating the procedure turn as well as including a statement “RADAR REQUIRED” as part of the procedure. The initial approach segment of these

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

instrument procedures is being provided by ATC radar vectors. Without ATC radar vectoring, the instrument procedure may not have a published initial approach segment.

Should an aircraft communication failure occur while being vectored for one of these approaches, refer to the communications failure procedures detailed in ATC Instrument Flight Rules (IFR) — General para 6.3.2.

9.7.3 Speed Adjustment — Radar Controlled Aircraft

NOTE: This section is for information only. It describes directives to controllers and in no way alters the application of CAR 602.32, which prescribes the following maximum speeds for all aircraft:

- below 10,000 feet ASL, 250 KIAS; and
- below 3000 feet AGL and within 10 NM of controlled airports, 200 KIAS.

To assist with radar vectoring, it is sometimes necessary to issue speed adjustments, while ATC will take every precaution not to request speeds beyond the capability of the aircraft, it is the pilot's responsibility to ensure that the aircraft is not operated at an unsafe speed. If ATC issues a speed reduction that is inconsistent with safe operation, the pilot must inform ATC that he is unable to comply.

Speed adjustment will be expressed in units of 10 KIAS or multiples of 10 KIAS. Pilots complying with speed adjustment are expected to maintain a speed within 10 KIAS of the specified speed.

Pilots may be asked to:

- a. maintain present speed; or
- b. increase or reduce speed to a specified speed or by a specified amount.

Unless prior concurrence in the use of a lower speed is obtained from the pilot, the following minimum speeds will be applied to:

- a. aircraft operating 20 NM or more from destination airport:
 1. at or above 10,000 ft ASL: 250 KIAS; and
 2. below 10,000 ft ASL: 210 KIAS;
- b. turbojet aircraft operating less than 20 NM from destination airport: 160 KIAS; and
- c. propeller-driven aircraft operating less than 20 NM from destination airport: 120 KIAS.

Pilots of aircraft which cannot attain speeds as high as the minimum speeds specified above may be requested to:

- a. maintain a specified speed equivalent to that of a preceding or succeeding aircraft; or
- b. increase or decrease speed by a specified amount.

The issuance of an approach clearance normally cancels a speed adjustment; however, if the controller requires that a pilot maintain a speed adjustment after the issuance of the approach clearance, the controller will restate it. Otherwise, ATC may use the phrase "resume normal speed" to advise a pilot that previously issued speed restrictions are cancelled. Unless specifically

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

stated by ATC, an instruction to “resume normal speed” does not cancel speed restrictions that are applicable to published procedures of upcoming segments of flight.

9.7.4 Precision Radar Approaches

- a. Precision Radar Approaches (PARs) are provided at airports with military PAR units. The aircraft is vectored by surveillance radar to a predetermined position, at which point control is transferred to the PAR controller for the approach.

EXAMPLE: JULIETT WHISKEY CHARLIE, EIGHT MILES FROM AIRPORT, TURN LEFT HEADING TWO SEVEN ZERO FOR FINAL APPROACH. CLEARED FOR PRECISION RADAR APPROACH RUNWAY TWO FOUR. CONTACT TRENTON PRECISION ON ONE TWO EIGHT DECIMAL SEVEN NOW.

- b. In an emergency, where surveillance radar coverage permits it, air traffic controllers will provide a surveillance radar approach if no alternative method of approach is available and the pilot declares an emergency and requests a radar approach.

NOTE: NAV CANADA radars are not flight-checked or commissioned for surveillance approaches, nor are Nav Canada controllers specifically trained to provide them.

9.8 INITIAL CONTACT WITH CONTROL TOWERS

Pilots should establish contact with the control tower as follows:

- a. If in direct communication with an ACC or a TCU, the IFR controller shall advise the pilot when contact is to be made with the tower. Unless on radar vectors to final approach, pilots should give the tower their ETA to the facility for the approach they intend to fly.
- b. If the conditions above do not apply, pilots should establish communication with the tower when approximately 25 NM from the airport, give their ETA, obtain an ATC approach clearance (if not already received), advise approach intentions and remain on tower frequency.

NOTE: Whenever an ETA is passed, the pilot should specify the point, fix or facility to which the ETA applies.

9.9 APPROACH POSITION REPORTS — CONTROLLED AIRPORTS

Pilots conducting an instrument approach to, or landing at a controlled airport should only make position reports that are requested by the appropriate ATC unit. As an example, pilots may expect ATC to request a report by the Final Approach Fix (FAF) or a specified distance on final. Position reports made under these circumstances are expected to be stated by reporting the position only.

9.10 CONTROL TRANSFER — IFR UNITS TO TOWERS

Tower controllers may accept responsibility for control of an arriving IFR flight within the CZ if VMC exist at an airport, and the aircraft has been sighted and will remain in sight. The transfer of control to the tower does not cancel the IFR flight plan, but rather indicates that the aircraft is now receiving airport control service. In such instances, IFR separation minima may not continue to be applied. The tower controller may use visual separation procedures, or issue clearances and instructions as necessary to maintain a safe, orderly and expeditious flow of airport traffic. Occa-

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

sionally the tower controller may issue instructions that supersede previous instructions and clearances that the pilot had received from the IFR unit. Acknowledgement of these instructions indicates to the tower that the pilot shall comply with them. A pilot must not assume that the control tower has radar equipment or that radar service is being provided.

9.11 INITIAL CONTACT WITH AIR-TO-GROUND (A/G) FACILITY AT UNCONTROLLED AIRPORTS

Pilots shall establish communications with the A/G facility (FSS, RCO, CARS or UNICOM) on the appropriate frequency if in direct communication with an ACC or a TCU, when directed to do so by the ACC or TCU.

Notwithstanding this, in accordance with CAR 602.104, pilots shall establish communication with the facility on the appropriate frequency no later than five minutes prior to the estimated time of commencing the approach procedure. If the ATC approach clearance has not already been received, it should be obtained from the agency listed on the Jeppesen approach charts unless otherwise directed by ATC.

NOTE:

- a. If a pilot is instructed to remain on the ATC frequency rather than being transferred to the appropriate frequency for the uncontrolled airport, it remains the pilot's responsibility to notify the associated destination airport ground station, or to broadcast where no ground station exists, and report in accordance with the following subsection. This may be accomplished by taking one of the following actions:*
 - 1. if the aircraft is equipped with more than one two-way communication radio, the pilot is expected to make the report on the appropriate frequency with the secondary radio while monitoring the ATC frequency on the primary radio, or*
 - 2. if the aircraft is equipped with a single two-way communication radio, the pilot must first request and receive permission to leave the ATC frequency in order to transmit this directed or broadcast report and then return to the ATC frequency; or, if this is not possible, the pilot should specifically request ATC to notify the associated ground station of their approach intentions and estimated time of landing.*
- b. At airports where RAAS is provided via an RCO and where AWOS (or LWIS) weather information is also broadcast via a Voice Generator Module (VGM), it is recommended that pilots listen to the broadcast prior to contacting the A/G facility and upon contact, advise that they have the wind and altimeter information.*

Because a VGM weather broadcast contains up-to-the-minute weather, it will be more current and may differ slightly from the most recently disseminated aviation routine weather report (METAR) or aviation selected special weather report (SPECI). The latest METAR or SPECI for the remote airport will be provided, on request, from the ATS unit controlling the RCO.

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

9.12 IFR REPORTING PROCEDURES AT UNCONTROLLED AIRPORTS

Subsection 1 of CAR 602.104 — Reporting Procedures for IFR Aircraft When Approaching or Landing at an Uncontrolled Airport “applies to persons operating IFR aircraft when approaching or landing at an uncontrolled airport, whether or not the airport lies within an MF area.”

Subsection 2 of CAR 602.104 states:

The pilot-in-command of an IFR aircraft who intends to conduct an approach to or a landing at an uncontrolled airport shall report.

- a. the pilot-in-command's intentions regarding the operation of the aircraft
 1. five minutes before the estimated time of commencing the approach procedure, stating the estimated time of landing,
 2. when commencing a circling maneuver, and
 3. as soon as practicable after initiating a missed approach procedure; and
- b. the aircraft's position
 1. when passing the fix outbound, where the pilot-in-command intends to conduct a procedure turn, or, if no procedure turn is intended, when the aircraft first intercepts the final approach course,
 2. when passing the final approach fix or three minutes before the estimated time of landing where no final approach fix exists, and
 3. on final approach.

In addition to these requirements, pilots operating aircraft under IFR into an uncontrolled airport, when the weather conditions at the airport could permit VFR circuit operations, are expected to approach and land on the active runway that may be established by the aircraft operating in the VFR circuit. Pilots operating aircraft under IFR at an uncontrolled airport do not establish any priority over aircraft operating under VFR at that airport. Should it be necessary for the IFR aircraft to approach to and/or land on a runway contrary to the established VFR operation, it is expected that appropriate communications between pilots, or between pilots and the air-to-ground facility, will be effected in order to ensure there is no traffic conflict.

9.13 IFR PROCEDURES AT UNCONTROLLED AIRPORTS IN UNCONTROLLED AIRSPACE

Pilots operating IFR in uncontrolled airspace should, whenever practical, monitor 126.7 MHz and broadcast their intentions on this frequency immediately prior to changing altitude or commencing an approach. Therefore, when arriving at an airport where another frequency is designated as the MF, descent and approach intentions should be broadcast on 126.7 MHz before changing to the MF. If conflicting IFR traffic becomes evident, this change should be delayed until the conflict is resolved. Once established on the MF, the pilot shall make the reports listed in the subsection above.

A straight-in landing from an IFR approach should not be used at uncontrolled airports where air-ground advisory is not available to provide the *wind direction and speed* and runway condition

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

reports required to conduct a safe landing. The pilot should determine the wind, and verify the runway is unobstructed before landing. Where pilots lack any necessary information, they are expected to ensure that a visual inspection of the runway is completed prior to landing. In some cases, this can only be accomplished by conducting a circling approach using the appropriate circling MDA.

Pilots operating aircraft under IFR into uncontrolled airports in uncontrolled airspace when the weather conditions at the airport could permit VFR circuit operations, are expected to approach and land on the active runway that may be established by the aircraft operating in the VFR circuit. Pilots operating aircraft under IFR at uncontrolled airports in uncontrolled airspace do not establish any priority over aircraft operating VFR at that airport. Should it be necessary for the IFR aircraft to approach to, land, or takeoff on a runway contrary to the established VFR operation, it is expected that appropriate communications between the pilots will be effected in order to ensure that there is no conflict of traffic.

9.14 OUTBOUND REPORT

To apply the prescribed separation minima between aircraft intending to make a complete instrument approach procedure and other aircraft, ATC must often establish the position and direction of arriving aircraft with respect to the approach facility. When reporting “outbound”, pilots should make these reports only after they are over or abeam the approach facility, and proceeding in a direction away from the airport.

9.15 STRAIGHT-IN APPROACH

ATC uses the term “straight-in approach” to indicate an instrument approach conducted so as to position the aircraft on final approach without performing a procedure turn.

9.16 STRAIGHT-IN APPROACHES FROM AN INTERMEDIATE FIX

Published transitions normally are designated from an enroute navigation aid to the primary approach aid upon which the procedure turn is based. However, to accommodate aircraft with modern avionics equipment and to improve fuel economy, transitions at some locations direct the pilot to an intermediate fix (IF) on the final approach course. Subject to ATC requirements and local traffic conditions, a straight-in approach may be made from this fix.

Intermediate fixes are usually located on the final approach track at the procedure turn distance specified in the profile view. This distance, which is normally 10 NM, is the distance within which the procedure turn should be executed. Accordingly, after passing the fix and maneuvering the aircraft onto the proper inbound track, descent may be made to the appropriate published altitude that would apply as if a procedure turn had been completed.

The abbreviation “NoPT” is used to denote that no procedure turn is necessary from the point indicated and will normally be shown adjacent to the IF. However, if the minimum altitude IF to the final approach fix (FAF) is not readily apparent, the “NoPT” abbreviation may be shown at some point between the fix and FAF, along with an altitude applicable for this segment.

Where more than one transition intersects the final approach track at different points, only the furthest intersection is designated as the IF. Pilots may begin a straight-in approach from any depic-

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

ted transition that intersects the final approach track inside the designated IF, provided that ATC is aware of their intentions and subsequent maneuvering is within the capabilities of the aircraft.

If the aircraft is badly positioned, laterally or vertically, after being cleared by ATC for the straight-in approach, pilots should climb to the procedure turn altitude, or the minimum altitude at the facility if one is depicted, and proceed to the FAF requesting clearance for a procedure turn.

NOTE: If the FAF is behind the aircraft, the pilot must conduct a missed approach and request further clearance from ATC.

The depiction of radials on a DME arc transition to an IF are normally limited to the radial forming the IAF at the beginning of the arc, the lead radial (if required) to indicate where the turn to the final approach track should be commenced, and radials forming step-down fixes if descent to lower altitudes can be approved. However, the arc may be joined from any radial that intercepts the depicted arc.

9.17 PROCEDURE ALTITUDES AND CURRENT ALTIMETER SETTING

All altitudes published on the Jeppesen Approach Charts are minimum altitudes which meet obstacle clearance requirements when international standard atmosphere (ISA) conditions exist, and when the aircraft altimeter is set to the current altimeter setting for that airport. The altimeter setting may be a local or a remote setting when so authorized on the instrument approach chart. A current altimeter setting is one provided by approved direct reading or remote equipment, or by the most recent routine hourly weather report. These readings are considered current up to 90 minutes from the time of observation. Care should be exercised when using altimeter settings older than 60 minutes or when pressure has been reported as falling rapidly. In these instances, a value may be added to the published DH/MDA in order to compensate for falling pressure tendency (0.01 inches mercury = 10 feet correction). Under conditions of extreme cold, corrections to the published altitudes should be applied to ensure adequate obstacle clearance. When an authorized remote altimeter setting is used, the altitude correction shall be applied as indicated.

9.17.1 Corrections for Temperature

Pressure altimeters are calibrated to indicate true altitude under ISA conditions. Any deviation from ISA will result in an erroneous reading on the altimeter. In the case when the temperature is higher than the ISA, the true altitude will be higher than the figure indicated by the altimeter, and the true altitude will be lower when the temperature is lower than the ISA. The altimeter error may be significant and becomes extremely important when considering obstacle clearances in very cold temperatures.

The published minimum IFR altitudes (i.e. the MSA/TAA and the initial/intermediate/final and missed approach segments, including the MDA/DA) must be adjusted when the ambient temperature on the surface is much lower than that predicted by the standard atmosphere. As a general rule this is considered to be 0°C or, when MDAs/DAs are 1000 ft HAA or higher, it begins at 10°C.

NOTE: Should the pilot feel that the above rules do not adequately adjust the published minimum IFR altitudes in the procedures to compensate for low temperatures, it is at the pilot's discretion to apply temperature correction whenever the airport temperature is below the ISA.

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

Corrections may be obtained from the “Altitude Correction Chart” shown in table below. This chart is calculated for an airport at sea level. It is, therefore, conservative when applied to airports at higher altitudes. To calculate the corrections (reduced altitudes) for specific airports or altimeter setting sources above sea level, or for values not tabulated, refer to the following paragraphs.

With respect to altitude corrections, the following procedures apply:

- IFR assigned altitudes may be either accepted or refused. Refusal in this case is based upon the pilot's assessment of temperature effect on obstacle clearance. IFR assigned altitudes accepted by a pilot should not be adjusted to compensate for cold temperatures, i.e., if a pilot accepts “maintain 3000 ft”, an altitude correction should not be applied to 3000 ft.
- Vectored altitudes assigned by ATC are temperature corrected and require no temperature compensation by pilots.
- When altitude corrections are applied to a published mandatory altitude or missed approach holding altitude, pilots should advise ATC of the temperature-corrected altitude prior to crossing the associated waypoint.

The “Altitude Correction Chart” was calculated assuming a linear variation of temperature with height. It is based on the following equation, which may be used with the appropriate value of t_0 , H , L_0 and H_{ss} to calculate temperature corrections for specific conditions. This equation produces results that are within five percent of the accurate correction for altimeter setting sources up to 10,000 ft and with minimum heights up to 5000 ft above that source. Unless otherwise specified, the destination airport elevation is used as the elevation of the altimeter source.

Altitude Corrections Based on Airport Cold Temperatures

A/D TEMP DEGREE C	HEIGHT ABOVE THE ELEVATION OF THE ALTIMETER SOURCE (feet)													
	200	300	400	500	600	700	800	900	1000	1500	2000	3000	4000	5000
0	20	20	30	30	40	40	50	50	60	90	120	170	230	290
-10	20	30	40	50	60	70	80	90	100	150	200	290	390	490
-20	30	50	60	70	90	100	120	130	140	210	280	430	570	710
-30	40	60	80	100	120	130	150	170	190	280	380	570	760	950
-40	50	80	100	120	150	170	190	220	240	360	480	720	970	1210
-50	60	90	120	150	180	210	240	270	300	450	600	890	1190	1500

NOTE:

- The corrections have been rounded up to the next 10 ft increment.
- Values should be added to published minimum IFR altitudes.
- Temperature values from the reporting station nearest to the position of the aircraft should be used. This is normally the airport.

CA 9
INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

Example of Corrections for an Airport at an Elevation of 2262 ft with a Temperature of -50°C

EXAMPLE: Airport Elevation 2262 ft			EXAMPLE: Airport Temperature -50°	
	ALTITUDE	HAA	CORRECTION	INDICATED ALTITUDE
Procedure Turn	4000 ft	1738 ft	+521.4 ft ¹	4600 ft ²
FAF	3300 ft	1038 ft	+311.4 ft	3700 ft
MDA Straight-in	2840 ft	578 ft	+173.4 ft	3020 ft
Circling MDA	2840 ft	578 ft	+173.4 ft	3020 ft

¹ CORRECTION derived as follows:

(2000 ft at -50° error) 600 - (1500 ft at -50° error) 450	= 150
Altitude difference of above (2000 - 1500)	= 500
Error per foot difference (150/500)	= .3
HAA	= 1738
Error at 1738 = (1738 - 1500) * 0.3 = 71.4 + 450 (error -50° at 1500)	= 521.4

² INDICATED ALTITUDE derived as follows:

Calculated error at 1738 from above	= 521.4
Procedure-turn altitude (4000) + error (521.4)	= 4521.4
INDICATED ALTITUDE rounded next higher 100-ft increment	= 4600

Figure 9.9 — Correction for Cold Temperatures: Equation

$$\text{Correction} = H \times \left(\frac{15 - t_0}{273 + t_0 - 0.5 \times L_o \times (H + H_{ss})} \right)$$

where:

H = minimum height above the altimeter setting source (the setting source is normally the airport, unless otherwise specified)

$t_0 = t_{\text{airport}} + L_o \times h_{\text{airport}}$ airport (or specified temperature reporting point) temperature adjusted to sea level

$L_o = 0.0065^\circ\text{C per meter or } 0.00198^\circ\text{C per foot}$

H_{ss} = altimeter setting source elevation

t_{airport} = airport (or specified temperature reporting point) temperature

h_{airport} = airport (or specified temperature reporting point) elevation

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

The actual lapse rate may vary considerably from the assumed standard, depending on latitude and time of year. However, the corrections derived from the linear approximation can be taken as a satisfactory estimate for general application at levels up to 10,000 ft.

9.17.2 Remote Altimeter Setting

Normally, approaches shall be flown using the current altimeter setting only for the destination airport. However, at certain airports where a local pressure setting is not available, approaches may be flown using a current altimeter setting for a nearby airport. Such an altimeter setting is considered a remote altimeter setting, and authorization for its use is published in the RASS box, located at the bottom left-hand corner of the approach chart, adjacent to the minima box, below the profile view. Jeppesen IACs display procedure source notes concerning where to obtain an altimeter setting in the Briefing Strip section and footnote the higher FAF crossing altitude in the profile, and depict both conditions in the minimums.

If the use of a remote altimeter setting is required for limited hours only, an altitude correction will be included with the authorization. When the remote altimeter setting is used, the altitude correction shall be applied as indicated. If the use of a remote altimeter setting is required at all times, then the correction is incorporated into the procedure at the time it is developed.

EXAMPLE:

- a. RASS: When using CYYY add 200'.

(When using the Mont-Joli altimeter setting, add 200 ft to the intermediate, final and missed approach segment minimum altitudes.)

- b. RASS: Use CYXU.

(Use London altimeter setting.)

If the altitude correction results in the calculated rate of descent exceeding design parameters, the words "circling minima apply" will be added to the RASS box. The intent of this note is to draw the pilot's attention to the fact that he/she cannot use straight-in minima when using the remote altimeter source. However, this does not prohibit the pilot from landing straight in if he/she has adequate visual reference in applying circling minima and the aircraft is suitably positioned to land straight in.

EXAMPLE:

RASS: When using CYHU add 120'. Circling minima apply.

(When using St-Hubert altimeter, add 120 ft to the intermediate, final and missed approach segment minimum altitudes; circling minima apply.)

9.18 DEPARTURE, APPROACH AND ALTERNATE MINIMA

The civil minima published shall, unless otherwise authorized, be observed by all pilots in accordance with their instrument rating as outlined in ATC Figure 9.10. Authorization to operate to special limits may be obtained by air carriers in accordance with CAR PART VII, or by private operators in accordance with CAR Subpart 604.

CA 9
INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES
9.18.1 Category II ILS Minima

Category II operations are precision approaches in weather minima as low as 100 feet DH and RVR 1200 feet. These minima are restricted to aircraft and pilots specifically approved for such operations by TC, and at runways specially equipped for the category of operation. Details on Category II requirements are contained in CAR 602.128 — Landing Minima and the Manual of All Weather Operations Categories II and III (TP 1490E).

Figure 9.10 — Instrument Rating Weather Minima for CAT II ILS Approach

	AIRPLANES	ROTORCRAFT
TAKEOFF VISIBILITY	As published on IFR Airport charts.	One-half that published on the IFR Airport chart but not less than 1/4 SM.
LANDING DH or MDA	As published on Instrument Approach Procedures.	As published on Instrument Approach Procedures.
ALTERNATE WEATHER MINIMA REQUIREMENTS		
FACILITIES AVAILABLE AT SUITABLE ALTERNATE	WEATHER REQUIREMENTS	
TWO OR MORE USABLE PRECISION APPROACHES Each providing straight-in minima to separate suitable runways.	400 – 1 or 200 – 1/2 above the lowest usable HAT and visibility, whichever is greater.	N/A
ONE USABLE PRECISION APPROACH	600 – 2* or 300 – 1 above the lowest usable HAT and visibility, whichever is greater.	N/A
NON-PRECISION ONLY AVAILABLE	800 – 2* or 300 – 1 above the lowest usable HAT/HAA and visibility, whichever is greater.	N/A
NO IFR APPROACH AVAILABLE	Forecast weather must be no lower than 500 ft above a minimum IFR altitude that will permit a VFR approach and landing.	N/A
FOR ROTORCRAFT Where instrument approach procedures are available.	N/A	Ceiling 200 ft above the minima for the approach to be flown, and visibility at least 1 SM but never less than the minimum visibility for the approach to be flown.

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

9.19 APPLICATION OF MINIMA**9.19.1 Take-Off Minima**

CAR 701.20 — Take-off Minima states that:

For the purposes of section 602.126, a person may conduct a take-off in an aircraft where weather conditions are below the take-off minima specified in the *Canada Air Pilot* if:

- a. in the case of a foreign air operator, the foreign air operator is authorized to do so in its Canadian foreign air operator certificate and complies with the *Commercial Air Service Standards*; or
- b. in the case of a person who operates a foreign state aircraft, the person is authorized to do so in a flight authorization and complies with the *Commercial Air Service Standards*.

Subsection (1) of CAR 602.126 — Take-off Minima states that:

No pilot-in-command of an aircraft shall conduct a take-off if the take-off visibility, as determined in accordance with subsection (2), is below the minimum take-off visibility specified in:

- a. the air operator certificate where the aircraft is operated in accordance with Part VII;
- b. a special authorization issued under subsection 604.05(2); or
- c. the *Canada Air Pilot* in any case other than a case described in paragraph a. or b.

Subsection (2) of CAR 602.126 states that:

For the purposes of subsection (1), the take-off visibility is:

- a. the RVR of the runway, if the RVR is reported to be at or above the minimum take-off visibility specified in a document or the manual referred to in subsection (1);
- b. the ground visibility of the airport for the runway, if the RVR
 1. is reported to be less than the minimum take-off visibility specified in a document or the manual referred to in subsection (1),
 2. is reported to vary between distances less than and greater than the minimum take-off visibility specified in the *Canada Air Pilot* or a certificate referred to in subsection (1), or
 3. is not reported; or
- c. the runway visibility as observed by the pilot-in-command, if
 1. the RVR is not reported, and
 2. the ground visibility of the airport is not reported.

With respect to take-off visibility, pilots will be advised of the ground visibility by the appropriate ATS unit. In the following example, explanations are provided to illustrate whether take-off is authorized in a variety of visibility conditions.

EXAMPLE: A take-off is to be conducted from Runway 27; the pilot is authorized a take-off minimum of RVR 2600 (1/2 SM).

- a. ATC/FSS reports "...RVR Runway 27 is 2000, variable 1600-2800, visibility 1/2 mile".

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

Although the RVR variation may be below minimum, a take-off is authorized because the reported ground visibility of 1/2 mile is governing.

- b. ATC/FSS reports "...RVR Runway 27 is 2200, visibility observed on-the-hour 1/4 mile, visibility now 1/2 mile".

Although the RVR is below minimum, a take-off is authorized because the reported ground visibility of 1/2 mile is governing.

- c. ATC/FSS reports "...RVR 2600, visibility 1/4 mile".

A take-off is authorized since the lowest reported RVR is at or above minimum.

- d. ATC/FSS reports "...RVR Runway 27 is 2000, variable 1600-2800, visibility 1/4 mile".

A take-off is not authorized since both the lowest RVR and the reported ground visibility are below minimum.

- e. ATC/FSS reports "...RVR Runway 27 is 2000...".

A take-off is not authorized because the reported RVR is below minimum.

- f. ATC/FSS/CARS reports only "...visibility observed on-the-hour 1/4 mile".

A take-off is not authorized because reported visibility is below minimum.

In summary a take-off is authorized when:

- the lowest reported RVR for the runway is at or above the minimum take-off visibility, regardless of reported ground visibility;
- the reported ground visibility for the airport is at or above the minimum take-off visibility, regardless of the reported RVR for the runway; or
- in the absence of a reported RVR or reported ground visibility, the runway visibility as observed by the pilot-in-command is at or above minimum take-off visibility.

9.19.2 Approach Ban

9.19.2.1 *General Aviation—Non-Precision Approach (NPA), Approach Procedure with Vertical Guidance (APV), CAT I or CAT II Precision Approach*

(Commercial Operators, See ATC 9.19.2.3 Approach Ban—Commercial Operators)

CAR 602.129 specifies that instrument approaches by general aviation aircraft are governed by RVR values only. With certain exceptions, pilots of aircraft are prohibited from completing an instrument approach past the FAF (or where there is no FAF, the point where the final approach course is intercepted) to a runway served by an RVR, if the RVR values as measured for that runway are below the following minima:

CA 9
INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

MINIMUM RVR

MEASURED RVR*	FIXED WING	ROTORCRAFT
RVR "A" ONLY	1200	1200
RVR "A" AND "B"	1200 / 600	1200 / 0
RVR "B" ONLY	1200	1200
*RVR "A" located adjacent to the runway threshold. RVR "B" located adjacent to the runway mid-point.		

The following exceptions to the above prohibitions apply to all aircraft when:

- a. the below-minima RVR report is received, the aircraft is inbound on approach and has passed the FAF, or when there is no FAF, the point where the final approach course is intercepted;
- b. the pilot-in-command has informed the appropriate ATC unit that the aircraft is on a training flight and that the pilot-in-command intends to initiate a missed approach procedure at or above the DH or MDA, as appropriate;
- c. the RVR is varying between distances less than and greater than the minimum RVR;
- d. the RVR is less than the minimum RVR, and the ground visibility at the airport where the runway is located is reported to be at least one-quarter statute mile; or
- e. the pilot-in-command is conducting a precision approach to CAT III minima.

With respect to approach restrictions, in the case of a localized phenomenon or any fluctuations that effect RVR validity, where the ground visibility is reported by ATC or FSS to be at or above one-quarter statute mile, an approach may be completed.

EXAMPLE: An ILS approach is to be conducted to runway 27; RVR sensors are located at positions A and B; the pilot is flying an airplane.

- a. ATC/FSS reports "...RVR "A" 800, RVR "B" 800, observed visibility one-quarter statute mile."
An approach to DH/MDA is authorized because the reported ground visibility of one-quarter statute mile is governing.
- b. ATC/FSS reports "...RVR "A" not available, RVR "B" 1000."
An approach to DH/MDA is not authorized since RVR "B" is governing and is below RVR 1200 ft.

If after commencing an approach (but before reaching the FAF, or where there is no FAF, the point where the final approach course is intercepted), a pilot must discontinue an approach because the RVR has gone below minima, the pilot shall continue as cleared, advise ATC of their intentions and request further clearance. If further clearance is not received by the time the aircraft reaches the FAF, or where there is no FAF, the point where the final approach course is

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

intercepted, the pilot shall execute a missed approach and proceed via the missed approach procedure to the specified missed approach clearance limit.

In summary, an approach is authorized whenever:

- the lowest reported RVR for the runway is at or above minima (CAR 602.129), regardless of reported ground visibility;
- the RVR is reported to be varying between distances less than and greater than the minimum RVR;
- the RVR is below the minimum, and the ground visibility is reported to be at least one-quarter statute mile;
- the RVR for the runway is unavailable or not reported; or
- ATS is informed that an aircraft is on a training flight and will conduct a planned missed approach.

No pilot shall commence an NPA, an APV, or a CAT I or CAT II precision approach to an airport where low-visibility procedures are in effect. Low-visibility procedures are associated with CAT III operations. They are specified for an airport (for example, CYVR or CYYZ) in the Terminal Charts and restrict aircraft and vehicle operations on the movement area of the airport when the RVR is less than 1200 ft.

9.19.2.2 Approach Ban—General Aviation—CAT III Precision Approach

(Commercial Operators, see ATC 9.19.2.3 Approach Ban—Commercial Operators)

CAR 602.130 specifies the general aviation CAT III precision approach ban. No pilot shall continue a CAT III precision approach in an IFR aircraft beyond the FAF inbound, or where there is no FAF, the point where the final approach course is intercepted, unless the RVR reported is equal to or greater than the minimum RVR specified in the Terminal Charts in respect of the runway or surface of intended approach for the IAP conducted.

MINIMUM RVR—AIRCRAFT—CATIII

Measured RVR*	CAT IIIA	CAT IIIB	CAT IIIC
RVR “A”, “B” and “C”	600/600/600	Not Authorized	Not Authorized
*RVR “A” located adjacent to the runway threshold. RVR “B” located adjacent to the runway mid-point. RVR “C” located adjacent to the runway end.			

9.19.2.3 Approach Ban—Commercial Operators—General—Non-Precision Approach (NPA), Approach Procedure with Vertical Guidance (APV), or CAT I Precision Approach

CAR 700.10 specifies the NPA, APV and precision approach ban that generally applies to commercial operators. With certain exceptions, pilots of commercial aircraft are prohibited from completing an NPA, an APV, or a CAT I precision approach past the FAF inbound, or where there is

CA 9
INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

no FAF, the point where the final approach course is intercepted, if the visibility report is below the value corresponding to the Terminal Chart advisory visibility for the approach conducted.

MINIMUM VISIBILITY—AIRPLANES—NPA, APV, OR CAT I	
CAP ADVISORY VISIBILITY (SM, RVR x100 FT)	VISIBILITY REPORT (Grnd Vis SM, RVR “A” or Rwy Vis Ft)
1/2 RVR 26	3/8, RVR or Rwy Vis 1600
3/4 RVR 40	5/8, RVR or Rwy Vis 3000
1 RVR 50	3/4, RVR or Rwy Vis 4000
1 1/4	1, RVR or Rwy Vis 5000
1 1/2	1 1/4, RVR or Rwy Vis 6000
1 3/4	1 1/2, RVR or Rwy Vis > 6000
2	1 1/2, RVR or Rwy Vis > 6000
2 1/4	1 3/4, RVR or Rwy Vis > 6000
2 1/2	2, RVR or Rwy Vis > 6000
2 3/4	2 1/4, RVR or Rwy Vis > 6000
3	2 1/4, RVR or Rwy Vis > 6000

MINIMUM VISIBILITY	
MEASURED RVR	HELICOPTERS
RVR “A” only	1200
RVR “A” and “B”	1200/0
RVR “B” only	1200

An RVR report takes precedence over a runway visibility report or a ground visibility report, and a runway visibility report takes precedence over a ground visibility report. Ground visibility will only impose an approach ban at airports south of 60° N latitude. If no RVR, runway visibility, or ground visibility is reported, there are no criteria to impose an approach ban. (This concept is similar to the present CAR 602 approach ban, where if there is no RVR reported, there is no criterion to impose and approach ban.)

The following exceptions to the above prohibitions apply to all aircraft when:

- the visibility report is below the required value, and the aircraft has passed the FAF inbound, or where there is no FAF, the point where the final approach course is intercepted;
- the pilot-in-command has informed the appropriate ATC unit that the aircraft is on training flight and the pilot-in-command intends to initiate a missed approach procedure at or above the decision altitude (height) [DA(H)] or the MDA, as appropriate.

CA 9
INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

- c. the RVR is varying between distances less than and greater than the minimum RVR;
- d. the ground visibility is varying between distances less than and greater than the minimum visibility;
- e. a localized meteorological phenomenon is effecting the ground visibility to the extent that the visibility on the approach to the runway of intended approach and along that runway, as observed by the pilot in flight and reported immediately to ATS, if available, is equal to or greater than the visibility specified in the Terminal Chart for the IAP conducted; or
- f. the approach is conducted in accordance with an Operations Specification issued in accordance with CAR 703, 704 or 705.

No pilot shall commence an NPA, an APV, or a CAT I precision approach to an airport where low-visibility procedures are in effect. Low-visibility procedures are associated with CAT III operations. They are specified for an airport (for example, CYVR or CYYZ) in the Terminal Charts and restrict aircraft and vehicle operations on the movement area of the airport when the RVR is less than 1200 ft.

9.19.2.4 *Approach Ban—Commercial Operators—CAT II and CAT III Precision Approach*

CAR 700.11 specifies the CAT II and CAT III precision approach ban that applies to commercial operators. No pilot shall continue a CAT II or CAT III precision approach in an IFR aircraft beyond the FAF inbound, or where there is no FAF, the point where the final approach course is intercepted, unless the RVR reported is equal to or greater than the minimum RVR specified in the Terminal Chart in respect of the runway or surface of intended approach for the IAP conducted.

MINIMUM RVR—CAT II		
MEASURED RVR*	AEROPLANES	HELICOPTERS
RVR “A” only	1200	1200
RVR “A” and “B” only	1200/600	1200/0
RVR “B” only	1200	1200

MINIMUM RVR—AIRCRAFT—CAT III			
MEASURED RVR*	CAT IIIA	CAT IIIB	CAT IIIC
RVR “A”, “B” and “C”	600/600/600	Not Authorized	Not Authorized
*RVR “A” located adjacent to the runway threshold. RVR “B” located adjacent to the runway mid-point. RVR “C” located adjacent to the runway end.			

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

9.19.2.5

Approach Ban—Commercial Operators—Operations Specification—Non-Precision Approach (NPA), Approach Procedure with Vertical Guidance (APV), CAT I Precision Approach

CARs 703.41, 704.37, and 705.48 specify the NPA, APV and precision approach ban that applies to commercial operators through Operations Specification. CAR 703, 704 and 705 operators through an Operations Specification 019, 303 or 503 and who meet all the conditions related to the approach procedure, are permitted to conduct an approach at a visibility value less than those specified in the CAR 700 approach ban. With certain exceptions, pilots of commercial aircraft are prohibited from completing an NPA, an APV, or a CAT I precision approach past the FAF inbound, or where there is no FAF, the point where the final approach course is intercepted, if the visibility report is below the value corresponding to the Terminal Chart advisory visibility for the approach conducted.

MINIMUM VISIBILITY—AIRPLANES—703/704/705 OPERATIONS SPECIFICATION—NPA, APV, OR CAT I	
CAP ADVISORY VISIBILITY (SM, RVR x100 FT)	VISIBILITY REPORT (Grnd Vis SM, RVR “A” or Rwy Vis Ft)
1/2 RVR 26	1/4, RVR or Rwy Vis 1200
3/4 RVR 40	3/8, RVR or Rwy Vis 2000
1 RVR 50	1/2, RVR or Rwy Vis 2600
1 1/4	5/8, RVR or Rwy Vis 3400
1 1/2	3/4, RVR or Rwy Vis 4000
1 3/4	1, RVR or Rwy Vis 5000
2	1, RVR or Rwy Vis 5000
2 1/4	1 1/4, RVR or Rwy Vis 6000
2 1/2	1 1/4, RVR or Rwy Vis > 6000
2 3/4	1 1/2, RVR or Rwy Vis > 6000
3	1 1/2, RVR or Rwy Vis > 6000

An RVR report takes precedence over a runway visibility report or a ground visibility report, and a runway visibility report takes precedence over a ground visibility report. Ground visibility will only impose an approach ban at airports south of 60° N latitude. If no RVR, runway visibility, or ground visibility is reported there are no criteria to impose an approach ban. (This concept is similar to the present CAR 602 approach ban, where if there is no RVR reported, there is no criterion to impose an approach ban.

The following exceptions to the above prohibitions apply to airplanes when:

- the visibility report is below the required value and the aircraft has passed the FAF inbound, or where there is no FAF, the point where the final approach course is intercepted: or

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

- b. the RVR is varying between distances less than and greater than the minimum RVR.

9.19.2.6 Runway Visibility

CAR 602.131 specifies the concept of runway visibility as defined in CAR 101.01(1). The purpose of runway visibility is to determine and report a visibility at the TDZ of a runway that is not equipped with or is not reporting an RVR. An instrument-rated pilot or a qualified person (under CAR 804) can assess runway visibility when RVR sensor detection equipment is not available. In effect, a person is permitted to assess runway visibility from approximately the same position as an RVR "A" sensor installation. CAR Standard 622.131 (for pilots) and CAR Standard 824.25 (for qualified persons) describe how to assess and report runway visibility.

Runway visibility is assessed at or adjacent to the runway threshold, in the direction of the runway, based on runway lights or landmarks that can be seen and recognized. The assessment is made in feet based on a 200-ft runway edge light spacing, or using landmarks found on the applicable terminal chart. A report of runway visibility should be reported immediately to ATS in the following format:

"RUNWAY VISIBILITY, RUNWAY [runway number] ASSESSED AS [distance assessed] FEET AT [time] UTC," to the nearest 100-ft increment.

A runway visibility report is valid for a period of 20 min after it is assessed. If the runway visibility varies during assessment, the lowest value is reported. The lowest value that is reported is 200 ft, with lower values reported as "...LESS THAN 200 FEET..." The highest value that is reported is 6000 ft, with higher values reported as "...GREATER THAN 6000 FEET..."

9.19.2.7 Localized Phenomenon

CAR 700.10 recognizes that certain localized meteorological conditions can reduce the reported ground visibility, thus imposing an approach ban when the flight visibility appears to be much greater. An example would be a localized fog bank that is covering the ground observer's observation point, resulting in a reported ground visibility of one-quarter statute mile at an airport south of 60° N latitude, while the flight visibility along the approach to the runway and on the runway itself (as observed by the pilot-in-command), is greater than 15 SM. In this case, the pilot can declare a localized phenomenon, and override an approach ban imposed by a ground visibility report. A pilot cannot use localized phenomena to override an RVR or runway visibility report that imposes an approach ban. To legally continue the approach past the FAF inbound, the flight visibility on the approach path and along the runway must be equal to or greater than the advisory visibility published in the Terminal Charts, for the procedure flown, and the pilot-in-command must immediately report the conditions observed to ATS.

CAUTION: Pilots are reminded of the insidious hazard that thin ground-based layers, such as shallow fog, ice fog, or blowing snow can present. Such conditions may allow a pilot-in-command to override an approach ban based on what appears to be a localized phenomenon, when in fact extensive and very poor visibility will be encountered at low altitude during the later stages of the approach, landing and roll-out. The pilot-in-command should take all possible information into account before overriding an approach ban, based on what appears to be localized phenomenon, in order to avoid conducting an approach during these hazardous conditions.

CA 9
INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES
9.19.2.8
Effects of the High Intensity Approach Lighting (HIAL) System on Canada Air Pilot (CAP) Advisory Visibilities and Runway Certification

Instrument approach procedures developed for runways with HIAL systems receive a credit against their CAP advisory visibility (by up to ½ SM). When these lighting systems are inoperative, adjustments to the approach minima must be made by the pilot as indicated in the tables below. This includes cases when the HIAL system is continuously operating on only one of the normally available intensity levels and changes to the intensity cannot be selected or requested by the pilot during the approach. These approach minima adjustments may determine whether or not the pilot is prohibited from completing an instrument approach past the FAF (see Approach Ban).

HIAL systems in Canada include SSALR (“AN” in the CAP), ALSF-2 (“AL” in the CAP), and SSALS (“AW” in the CAP). Also included are the following older type systems: *CAT I High Intensity* (also known as ALSF-1 or as “AE” in the CAP) and *CAT II High Intensity* (“AC” in the CAP). All of these systems, except for SSALS, are used to certify a precision approach runway.

When the HIAL system is inoperative, a certified precision runway is downgraded to a non-precision runway. For this reason, an approach procedure with straight-in minima below a DH of 250 ft and below an advisory visibility of 1 SM (RVR 50) must have its minima increased to 250 ft DH and 1 SM (RVR 50) visibility when the HIAL is inoperative. For example:

Straight-in Minima Corrections for a DH below 250 ft

HIAL Operational (published)		HIAL Inoperative	
DH (ft)	Advisory Visibility (SM)	DH (ft)	Advisory Visibility (SM)
200 - 249	½ (RVR 26)	250	1 (RVR 50)

For approach procedures with straight-in minima of 250 ft DH/HAT or greater, the advisory visibility must be increased if any of the HIAL systems become inoperative, as indicated in the following table. No increase to the DH/HAT itself is required.

No adjustment to circling minima is required based on the operating condition of the HIAL systems.

Advisory Visibility Corrections for a DH Equal to or Greater than 250 ft

DH/HAT (ft)	Advisory Visibility when HIAL is Operational (published) (SM)	Advisory Visibility when HIAL is Inoperative (SM)
250 – 347	1	1
348 – 434	1	1 ¼
435 – 521	1	1 ½
522 – 608	1 ¼	1 ¾

CA 9
INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

Advisory Visibility Corrections for a DH Equal to or Greater than 250 ft (continued)

DH/HAT (ft)	Advisory Visibility when HI-AL is Operational (published) (SM)	Advisory Visibility when HI-AL is Inoperative (SM)
609 – 695	1 ½	2
696 – 782	1 ¾	2 ¼
783 – 869	2	2 ½
870 – 956	2 ¼	2 ¾
957 and above	2 ½	3

9.19.3 Landing Minima

CAR 602.128 specifies that landings are governed by published DH/MDAs. Pilots of aircraft on instrument approaches are prohibited from continuing the final approach descent below DH or descending below MDA, as applicable, unless the required visual reference has been established and maintained in order to complete a safe landing. When the required visual reference is not established or maintained, a missed approach must be initiated. Pilots must be cautioned that the missed approach segment that provides for obstacle clearance originates at the published Missed Approach Point (MAP). The published MAP on a precision approach is coincidental with the DH. Obstacle clearance will not be assured for missed approaches initiated beyond the MAP.

NOTE: Certain published approaches that contain multiple lines of minima may have step-down altitudes that are lower than a published line of minima. Pilots should not descend to a step-down altitude that is lower than the altitude on their selected line of minima.

The visual references required by the pilot to continue the approach to a safe landing should include at least one of the following references for the intended runway, and should be distinctly visible and identifiable to the pilot by:

- a. the runway or runway markings;
- b. the runway threshold or threshold markings;
- c. the touchdown zone or touchdown zone markings;
- d. the approach lights;
- e. the approach slope indicator system;
- f. the runway identification lights;
- g. the threshold and runway end lights;
- h. the touchdown zone light;
- i. the parallel runway edge lights; or
- j. the runway center line lights.

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

Airports that have instrument approaches may not have all of the above items, therefore, pilots should consult the appropriate charts and current NOTAM to ascertain the available aids.

Published landing visibilities associated with all instrument approach procedures are advisory only. Their values are indicative of visibilities which, if prevailing at the time of approach, should result in required visual reference being established. They are not limiting and are intended to be used by pilots only to judge the probability of a successful landing when compared against available visibility reports at the airport to which an instrument approach is being carried out.

9.20 RUNWAY VISUAL RANGE

9.20.1 Definitions

Prevailing Visibility — The maximum visibility value common to sectors comprising one-half or more of the horizontal circle.

NOTE: Prevailing Visibility is determined by human observations.

Runway Visual Range (RVR) — In respect of a runway, means the maximum horizontal distance, as measured by an automated visual landing distance system and reported by an ATC unit or an FSS for the direction of takeoff or landing, at which the runway, or the lights or markers delineating it, can be seen from a point above its center line at a height corresponding to the average eye level of pilots at touchdown.

To compute RVR, three factors must be known. The first is the transmissivity of the atmosphere as provided by a visibility sensor. The second is the brightness of the runway lights which is controlled on request by the ATC controller. The third factor is whether it is day or night, since the eye can detect lights easier at night than during the day. There is a period during twilight where there is a problem similar to that with prevailing visibility when neither day, nor night conditions prevail.

RVR is measured by a visibility sensor such as a transmissometer located near the runway threshold. For CAT II landing systems, a second sensor is provided about the mid-point of the runway. The transmissometer near the threshold is identified as "A" and the second one as "B". Their locations are important for the assessment of visibility, and so their positions are indicated on the airport diagrams.

A light emitted from a source is attenuated in the atmosphere due to snow, fog, rain and so forth. The amount of this attenuation, or the transmissivity of the atmosphere, can be obtained by measuring the amount of light reaching a detector after being transmitted by a projector. The visibility sensor samples the atmosphere at a height that best represents the slant transmittance from the pilot's eye at cockpit level to the runway.

9.20.2 Operational Use of RVR

RVR information is available at the ATC IFR arrival control position, the PAR position, the control tower, the FSS, and some EC weather stations.

When applicable, RVR information is given to the pilot as a matter of routine and can be used in the determination or application of visibility minima only if the active runway is served by the visibility sensor. RVR information, found in the remarks section of surface weather reports, is not to

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

be used for operational purposes and is superseded by any RVR information from ATS personnel.

NOTE: RVR reports are intended to provide an indication of how far the pilot can expect to see along the runway in the touchdown zone; however, the actual visibility at other points along the runway may differ due to the differing weather conditions. This should be taken into account when decisions must be made based on reported RVR.

A pertinent phenomenon that occurs fairly often during periods of low visibility is the large fluctuations that occur over extremely short time intervals. As per ICAO recommendations, the RVR computer automatically averages the readings over the last minute.

The controller will provide the RVR if it is less than 6000', or upon request. The RVR will be provided in 100 feet increments from 300 feet to 1199', in 200 feet increments from 1200' to 2999' and in 500 feet increments from 3000' to 6000'. The RVR remains constant for runway light settings of 1, 2 and 3, but it can increase for settings of 4 and 5. If the latter settings are used, the pilot will be provided with both the RVR and the light setting.

NOTE: At airports equipped with ARCAL, the light settings may not be known at ATS personnel.

In daytime, even a high intensity setting can fade into background brightness. For example, the pilot may be provided with an RVR of 4000' while making an approach when shallow fog is occurring over a snow surface in bright sunlight. Because of the glare, runway lights will be difficult to see, therefore visibility will be much less than the reported RVR. In situations such as this, the use of prevailing visibility would be more appropriate.

RVR may be used instead of prevailing visibility for landing and takeoff minima, but only for runways equipped with an RVR system. In such cases, the following table can be used.

GROUND VISIBILITY	RVR
1 mile	5000 feet
3/4 mile	4000 feet
1/2 mile	2600 feet
1/4 mile	1400 feet
See Note	under 1200 feet

NOTE 1: A comparative scale converting RVR-feet into RVR-meters is shown in the GEN section.

NOTE 2: Ground visibility does not apply to operators with a takeoff limit below 1200'.

ATS phraseology applicable to the foregoing is as follows:

Runway (number) visual range/RVR three thousand six hundred feet.

Runway (number) visual range/RVR less than three hundred feet.

Runway (number) visual range/RVR more than six thousand feet.

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

Runway (number) visual range/RVR (number) feet, fluctuating (number) to (number) feet, visibility (fraction) mile.

Runway (number) visual range/RVR (number) feet, runway lights at setting four/five.

Runway (number) visual range/RVR ALFA (number) feet, BRAVO (number) feet, CHARLIE (number) feet.

9.21 AIRCRAFT APPROACH CATEGORIES

Aircraft performance has a direct effect on the airspace and visibility required for the various maneuvers associated with the conduct of an instrument approach procedure. The most significant performance factor is aircraft speed. For this reason, a number of aircraft approach categories, each with a specified speed range, have been established.

An aircraft's approach category is determined based on its reference landing speed (V_{ref}), if specified, or if V_{ref} is not specified, 1.3 times stall speed (V_{so}) at the maximum certificated landing weight. V_{ref} , V_{so} , and the maximum certificated landing weight are those values as established for the aircraft by the certification authority of the country of registry. The categories are as follows:

CATEGORY	A	B	C	D	E
SPEEDS	up to 90 KIAS (includes all rotorcraft)	91 to 120 KIAS	121 to 140 KIAS	141 to 165 KIAS	above 165 KIAS

NOTE: Category E minima are not provided for on civil instrument approach procedure charts.

An aircraft's approach category does not change if the actual landing weight is less than the maximum certificated landing weight. The certificated approach category is permanent and independent of the changing conditions of day-to-day operations. An aircraft is certificated in only one approach category and cannot be flown to the minima of a slower approach category. For example, a Category C aircraft cannot utilize Category B minima.

However, if the requirement for a faster approach speed places the aircraft in a higher speed approach category, the minima for the appropriate higher category must be used. This may be due to operational circumstances such as emergency returns requiring overweight landing or approaches made with inoperative flaps or in icing conditions. Additionally, if it is necessary to visually maneuver at speeds in excess of the upper limit of a speed range for a category, the minima for the category for that higher speed must be used. For example, an aircraft which falls in Category A, but is circling to land at a speed in excess of 90 kt, must use the approach Category B minima when circling to land.

9.22 STRAIGHT-IN LANDING MINIMA

Minima for a straight-in landing are published when a normal rate of descent can be made from the final approach fix (FAF) to the runway threshold, and when the final approach track intersects the extended runway center line within 30° and within a prescribed distance from the threshold. When either the normal rate of descent or the runway alignment exceeds the criteria, straight-in landing minima are not published and only circling minima apply. The fact that only circling

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

minima are published does not preclude a pilot from landing straight-in if the required visual reference is available in sufficient time to make a normal approach and landing.

NOTE: The term straight-in landing minima should not be confused with the term straight-in approach minima (ATC 9.16). An ATC clearance for a straight-in approach merely clears the aircraft for an approach without first completing a procedure turn. The minima that will subsequently be used will be based on considerations such as the runway in use, published minima, aircraft category, etc.

The use of straight-in landing minima is predicated upon the pilot having the wind direction and speed and runway condition reports required to conduct a safe landing. At an uncontrolled airport where the pilot may lack the necessary information, the pilot is expected to verify that the runway is unobstructed prior to landing. In some cases, this can only be accomplished by conducting a circling approach using the appropriate circling minima.

At an uncontrolled airport, runway conditions (including any temporary obstructions such as vehicles) may be determined by the pilot by:

- a. contacting the appropriate FSS or UNICOM at the destination;
- b. a preflight telephone call to the destination to arrange for making the necessary information available when required for landing;
- c. a visual inspection;
- d. a NOTAM issued by the airport operator; or
- e. any other means available to the pilot, such as message relay from preceding aircraft at the destination.

9.23 CIRCLING

Circling is the term used to describe an IFR procedure that is conducted by visually maneuvering an aircraft, after completing an instrument approach, into position for landing on a runway which is not suitably located for a straight-in landing (not usually applicable to rotorcraft).

The visual maneuvering area for a circling approach is determined by drawing arcs centered on each runway threshold, and joining those arcs with tangent lines. The radius of the arcs is related to the aircraft category and may be based on either standard circling approach radii or expanded circling approach radii (see sections 9.23.1 and 9.23.2 below). The circling minimum descent altitude (MDA) provides a minimum of 300 feet above all obstacles within the visual maneuvering area for each category.

CA 9
INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

Figure 9.11 — Visual Maneuvering (Circling) Area

If it is necessary to maneuver an aircraft at a speed in excess of the upper limit of the speed range for its approach category, the circling minimum for the next higher category should be used in order to ensure appropriate protection from obstacles.

Circling restrictions are published at some locations to prevent circling maneuvers in certain sectors or directions where higher terrain or prominent obstacles exist. This practice allows the publication of lower minima than would otherwise be possible. In such cases, the circling MDA DOES NOT PROVIDE OBSTACLE CLEARANCE WITHIN THE RESTRICTED SECTOR.

9.23.1 Standard Circling Approach Radii

Circling approach protected areas developed prior to 2020 used the radius distances shown in the following table. Approaches using standard circling approach areas can be identified by the **absence** of the  symbol on the circling line of minima.

Standard Circling Approach Radii

Circling MDA in feet AMSL	Approach Category and Circling Radius (NM)				
	CAT A	CAT B	CAT C	CAT D	CAT E*
All altitudes	1.3	1.5	1.7	2.3	4.5

* Category E circling minima are published at DND airports only.

9.23.2 Expanded Circling Approach Radii

Circling approach protected areas developed in 2020 or later use a radius distance based on the aircraft category as well as the altitude of the circling MDA, which accounts for increases to true airspeed with altitude. The following table provides radius values for each aircraft category within five altitude bands. Approaches using expanded circling approach areas can be identified by the **presence** of the  symbol on the circling line of minima.

CA 9
INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

Expanded Circling Approach Radii

Circling MDA in feet AMSL	Approach Category and Circling Radius (NM)				
	CAT A	CAT B	CAT C	CAT D	CAT E*
1000 or less	1.3	1.7	2.7	3.6	4.5
1001 – 3000	1.3	1.8	2.8	3.7	4.6
3001 – 5000	1.3	1.8	2.9	3.8	4.8
5001 – 7000	1.3	1.9	3.0	4.0	5.0
7001 – 9000	1.4	2.0	3.2	4.2	5.3

* Category E circling minima are published at DND airports only.

9.24 CIRCLING PROCEDURES

An air traffic controller may specify maneuvering in a certain direction or area due to traffic considerations; however, the selection of the procedure required to remain within the protected area and to accomplish a safe landing rests with the pilot. There can be no single procedure for conducting a circling approach due to variables such as runway layout, final approach track, wind velocity and weather conditions. The basic requirements are to keep the runway in sight after initial visual contact, and remain at the circling MDA until a normal landing is assured. Examples of various circling approach situations are illustrated in Figure 9.12.

Figure 9.12 — Typical Circling Maneuvers

9.25 MISSED APPROACH PROCEDURE WHILE VISUALLY MANEUVERING IN THE VICINITY OF THE AIRPORT

The pilot may have to conduct a missed approach after starting visual maneuvers. There are no standard procedures in this situation. Thus, unless the pilot is familiar with the terrain, it is recommended that:

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

- a. a climb be initiated;
- b. the aircraft be turned towards the center of the airport; and
- c. the aircraft be established, as closely as possible, in the missed approach procedure published for the instrument approach procedure just completed.

With the runway in sight at circling MDA, the pilot should execute the missed approach if there is any doubt that the ceiling and visibility are adequate for maneuvering safely to the point of touchdown.

9.26 MISSED APPROACH PROCEDURES

Whenever a pilot conducts a published missed approach from an instrument approach procedure, the aircraft must continue along the published final approach course to the published Missed Approach Point (MAP) and follow the published missed approach instructions. The pilot may climb immediately to the altitude specified in the missed approach procedure or assigned by ATC. In the event of a missed approach when no missed approach clearance has been received, the pilot will follow the published missed approach instructions. Should the pilot arrive at the missed approach holding fix prior to receiving further clearance, the pilot will:

- a. hold in a standard holding pattern on the inbound track used to arrive at the fix;
- b. if there is a published missed approach track to the fix, hold in a standard holding pattern inbound to the fix on this track;
- c. if there is a published shuttle or holding pattern at the fix, hold in this pattern regardless of the missed approach track to the fix; or
- d. if there are published missed approach holding instructions, hold in accordance with these.

If a clearance to another destination has been received, the pilot shall, in the absence of other instructions, carry out the published missed approach instructions until at an altitude which will ensure adequate obstacle clearance before proceeding on course.

If specific missed approach instructions have been received and acknowledged, the pilot is required to comply with the new missed approach instructions before proceeding on course, e.g., "on missed approach, climb runway heading to 3000 feet; right turn, climb on course" or "on missed approach, climb straight ahead to the BRAVO NDB before proceeding on course".

Civil and military air traffic control procedures do not require the air traffic controller to provide terrain and obstacle clearance in their missed approach instructions. Terms such as "on missed approach, right turn climb on course" or "on missed approach, left turn on course" are not to be considered specific missed approach instructions. It remains the pilot's responsibility to ensure terrain and obstacle avoidance and clearance.

The terrain and obstacle environment in the missed approach segment may require a climb gradient greater than the standard 200 ft/NM (or 400 ft/NM for helicopter-only procedures). The pilot must plan in advance to ensure that the aircraft can meet the climb gradient required by the procedure in the event of a missed approach and must also be aware that flying at a ground speed higher than anticipated will increase the climb rate requirement (feet per minute). Where aircraft limitations or other factors preclude the pilot from following the published climb gradient, it is the

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

responsibility of the pilot-in-command (PIC) to determine alternative procedures that will take into account obstacle and terrain clearance.

**9.27 SIMULTANEOUS PRECISION INSTRUMENT APPROACHES —
PARALLEL RUNWAYS**

When simultaneous precision instrument approaches are in progress, ATC will vector arriving aircraft to one or the other of the parallel localizers for a straight-in final approach. (When cleared for a straight-in approach, a procedure turn is not permitted.) Each of the parallel approaches have a “high side” and a “low side” for vectoring and to allow for vertical separation until both aircraft are established inbound on their respective parallel localizer (LOC).

The pilot will be instructed to change and report on tower frequency prior to reaching the final approach fix (FAF) inbound. If an aircraft is observed to overshoot the localizer during the final turn, the pilot will be instructed to return to the correct localizer course immediately. After an aircraft is established on the localizer, the controller monitoring the final approach will issue control instructions only if an aircraft deviates or is expected to deviate by 1500 feet from the localizer center line. Information or instructions issued by the monitoring controller will be aimed at returning the aircraft to the localizer course. If the aircraft fails to take corrective action, the aircraft on the adjacent localizer may be issued appropriate control instructions. Monitoring of the approach is terminated without notification to the pilot when the aircraft is 1 NM from the runway threshold. If considered necessary, appropriate missed approach instructions will be issued.

THE APPROACH CLEARANCE WILL INCLUDE AN ALTITUDE THAT MUST BE MAINTAINED UNTIL INTERCEPTING THE GLIDE PATH. If the glide path is inoperative, the pilot will be cleared to maintain an altitude to a specified distance measuring equipment (DME) distance before commencing the descent.

When informed by automatic terminal information service (ATIS) or by the arrival controller that simultaneous precision instrument approaches are in progress, pilots should advise the arrival controller immediately of any avionics unserviceabilities having an impact on their capabilities to accept this procedure.

**9.28 SIMULTANEOUS PRECISION INSTRUMENT APPROACHES —
CONVERGING RUNWAYS**

ATC may clear pilots for precision instrument approaches simultaneously to converging runways at airports where this procedure has been approved.

Aircraft will be informed through ATIS or by the arrival controller as soon as feasible after initial contact when simultaneous precision instrument approaches to converging runways are in progress. When simultaneous approaches are in progress, ATC will vector arriving aircraft to the appropriate runway localizer for a straight-in final approach. Pilots should advise the arrival controller immediately of any malfunctioning or inoperative equipment making this procedure undesirable.

These are the restrictions for simultaneous precision approaches to converging runways:

- Converging runways (defined as an included angle between 15° and 100°).
- Radar available.

CA 9

INSTRUMENT FLIGHT RULES - ARRIVAL PROCEDURES

- Precision instrument approach systems (ILS/MLS) operating on each runway.
- Non-intersecting final approach courses.
- Missed approach points at least 3 NM apart.
- Non-overlapping primary missed approach protected airspace.
- Separate instrument approach charts denoting the procedures.
- If runways intersect, tower controllers must be able to apply visual separation as well as intersecting runway separation criteria.
- Only straight-in approaches and landing are authorized.

To emphasize the protection of active runways and to aid in preventing runway incursions, landing instructions which include the words “HOLD SHORT” should be acknowledged by a readback of the hold point by the pilot.

CA 10

INSTRUMENT FLIGHT RULES – HOLDING PROCEDURES

10 INSTRUMENT FLIGHT RULES — HOLDING PROCEDURES**10.1 GENERAL**

Pilots are expected to adhere to the aircraft entry and holding maneuvers, as described in ATC 10.5, since ATC provides lateral separation in the form of airspace to be protected in relation to the holding procedure.

10.2 HOLDING CLEARANCE

A holding clearance issued by ATC includes at least:

- a. clearance to the holding fix;
- b. direction to hold from the holding fix;
- c. a specified radial, course, or inbound track;
- d. if DME is used, the DME distances at which the fix end and outbound end turns are to be commenced [e.g., hold between (number of miles) and (number of miles).];

NOTE: In absence of an outbound DME being issued by ATC, pilots are expected to time the holding pattern in accordance with ATC 10.6.

- e. the altitude or FL to be maintained; and
- f. the time to expect further clearance or an approach clearance, or;
- g. the time to leave the fix in the event of a communications failure.

NOTE: An expect-further-clearance time usually is followed by further en route clearance, which is followed by an expect- approach-clearance time when traffic conditions permit.

During entry and holding, pilots manually flying the aircraft are expected to make all turns to achieve an average bank angle of at least 25° or a rate of turn of 3° per second, whichever requires the lesser bank. Unless the ATC clearance contains instructions to the contrary, or a non-standard holding pattern is published at the holding fix, pilots are expected to make all turns to the right after initial entry into the holding pattern.

Occasionally, a pilot may reach a clearance limit before obtaining further clearance from ATC. In this event, where a holding pattern is published at the clearance limit, the pilot is to hold as published. Where no holding pattern is published, the pilot is to hold in a standard pattern on the inbound track to such clearance limit and request further clearance. (See ATC 10.10 for procedure to be used when the holding pattern is published on enroute charts or terminal area charts.) If communication cannot be established with ATC, the pilot should then proceed in accordance with communication failure procedures as described in ATC 6.3.2.

EXAMPLE 1: A westbound flight on R77, cleared to Greely (YRR) NDB reaches YRR before obtaining further clearance. The pilot is to hold at YRR on an inbound track of 287° and request further clearance.

EXAMPLE 2: The published missed approach procedure for an ILS RWY 23 approach at Halifax is: "CLIMB TO 2200 feet ON TRACK OF 234° TO ZHZ NDB."

CA 10

INSTRUMENT FLIGHT RULES – HOLDING PROCEDURES

A pilot missing an ILS approach to RWY 23, and not in receipt of further clearance is to proceed directly to the ZHZ NDB, make a right turn and hold at the ZHZ beacon on an inbound track of 234° and request further clearance.

If for any reason a pilot is unable to conform to these procedures, ATC should be advised as early as possible.

10.3 STANDARD HOLDING PATTERN

A standard holding pattern is depicted in Figure 10.1 in terms of still air conditions.

Figure 10.1 — Standard Holding Pattern

- Having entered the holding pattern, on the second and subsequent arrivals over the fix, the pilot executes a right turn to fly an outbound track that positions the aircraft most appropriately for the turn onto the inbound track. When holding at a VOR, pilots should begin the turn to the outbound leg at the time of station passage as indicated on the TO-FROM indicator.
- Continue outbound for one minute if at or below 14,000 feet ASL, or one and a half minutes if above 14,000 feet ASL. (ATC specifies distance, not time, where a DME fix is to be used for holding.)
- Turn right so as to realign the aircraft on the inbound track.

10.4 NON-STANDARD HOLDING PATTERN

A non-standard holding pattern is one in which:

- the fix end and outbound end turns are to the left; and/or
- the planned time along the inbound track is other than the standard one-minute or one-and-a-half-minute leg appropriate for the altitude flown.

10.5 ENTRY PROCEDURES

The pilot is expected to enter a holding pattern according to the aircraft's heading in relation to the three sectors shown in Figure 10.2, recognizing a zone of flexibility of five degrees on either side of the sector boundaries. For holding on VOR intersections of VOR/DME/TACAN fixes, entries are limited to the radials or DME arcs forming the fix as appropriate.

CA 10
INSTRUMENT FLIGHT RULES – HOLDING PROCEDURES

Figure 10.2 — Entry Sectors

Sector 1 procedures (parallel entry) are:

- Upon reaching the fix, turn onto the outbound heading of the holding pattern for the appropriate period of time.
- Turn left to intercept the inbound track or to return directly to the fix.
- On the second arrival over the fix, turn right and follow the holding pattern.

Sector 2 procedures (offset entry) are:

- Upon reaching the fix, turn to a heading that results in a track having an angle of 30° or less from the inbound track reciprocal on the holding side.
- Continue for the appropriate period of time, then turn right to intercept the inbound track and follow the holding pattern.

Sector 3 procedure (direct entry) is:

- Upon reaching the fix, turn right and follow the holding pattern.

Entry procedures to a non-standard pattern requiring left turns are oriented in relation to the 70° line on the holding side (Figure 10.3), just as in the standard pattern.

CA 10

INSTRUMENT FLIGHT RULES – HOLDING PROCEDURES

Figure 10.3 — Left Hand Pattern Entry

When crossing the fix to enter a holding pattern, the appropriate ATC unit should be advised. ATC may also request that the pilot report “established in the hold”. The pilot is to report “established” when crossing the fix after having completed the entry procedure.

10.6 TIMING

The still air time for flying the outbound leg of a holding pattern should not exceed one minute if at or below 14,000 ft ASL, or one-and-a-half minutes if above 14,000 ft ASL; however, the pilot should make due allowance in both heading and timing to compensate the wind effect.

After initial circuit of the pattern, timing should begin abeam the fix or on attaining the outbound heading, whichever occurs later. The pilot should increase or decrease *outbound times, in recognition of winds, to effect 1 or 1 1/2 minutes (appropriate to altitude) inbound to the fix.*

When the pilot receives ATC clearance specifying the time of departure from the holding fix, adjustments should be made to the flight pattern within the limits of the established holding pattern to leave the fix as near as possible to the time specified.

10.7 SPEED LIMITATIONS

The size of the protected airspace for a holding pattern is based on aircraft speed. Unless otherwise noted on the charts or when a shuttle procedure is specified (see SHUTTLE PROCEDURE below), holding patterns must be entered and flown at or below the airspeeds listed in Table 10.1 below:

CA 10 INSTRUMENT FLIGHT RULES – HOLDING PROCEDURES

Table 10.1 — Maximum Holding Airspeeds

Altitude (ASL)	Maximum Holding Airspeed (KIAS)
At or below 6000 ft	200
Above 6000 ft up to and including 14,000 ft	230
Above 14,000 ft	265

NOTE:

- a. At Canadian military airfields, the size of the protected airspace is for a maximum of 310 KIAS, unless otherwise noted.
- b. For helicopter procedures (COPTER), the maximum holding airspeed is 90 KIAS, unless otherwise noted.

Pilots are to advise ATC immediately if airspeeds in excess of those specified above become necessary for any reason, including turbulence, or if they are unable to accomplish any part of the holding procedure.

After departing a holding fix, pilots should resume normal speed subject to other requirements, such as speed limitations in the vicinity of controlled airports, specific ATC requests, etc.

NOTE: In areas where turbulence is known to exist, holding patterns may be designed for speeds of 280 KIAS.

10.8 DME PROCEDURES

DME holding is subject to the same entry and holding procedures previously described except that distances, in NM, are used in lieu of time values. In describing the direction from the fix on which to hold and the limits of a DME holding pattern, an ATC clearance will specify the DME distance from the navigation aid at which the inbound and outbound legs are to be terminated. The end of each leg is determined by the DME indications.

Figure 10.4 — DME Hold

EXAMPLE: An aircraft cleared to the 270° RADIAL 10 MILE DME FIX, to HOLD BETWEEN 10 AND 15 MILES, will hold inbound on the 270° radial, commence turn to the outbound leg when the DME indicates 10 NM and commence turn to inbound leg when the DME indicates 15 NM.

CA 10

INSTRUMENT FLIGHT RULES – HOLDING PROCEDURES

10.9 SHUTTLE PROCEDURE

A shuttle procedure is defined as a maneuver involving a descent or climb in a pattern resembling a holding pattern. Shuttles are generally prescribed on instrument procedure charts located in mountainous areas. In the approach phase, it is normally prescribed where a descent of more than 2000 ft is required during the initial or intermediate approach segments. It can also be required when flying a missed approach or departure procedure from certain airports in the vicinity of mountain ranges. A shuttle procedure shall be executed in the pattern as published unless instructions contained in an ATC clearance direct otherwise.

To ensure that the aircraft does not exceed the obstacle clearance protected airspace during a shuttle descent or climb, the aircraft must not exceed:

- a. the airspeed limit published on instrument procedure charts or, if no airspeed limit is published, the following limits:
 1. For climbs, the maximum airspeed is 310 KIAS.
 2. For descents, the maximum airspeeds from Table 10.1 apply;
- b. the outbound/inbound still air time restrictions;
- c. the DME holding restrictions.

NOTE: All shuttle climb airspeeds are subject to CAR 602.32.

10.10 HOLDING PATTERNS PUBLISHED ON ENROUTE AND TERMINAL CHARTS

At some high traffic density areas, holding patterns are depicted on IFR terminal area and enroute charts. When pilots are cleared to hold at a fix where a holding pattern is published, or if clearance beyond the fix has not yet been received, pilots are to hold according to the depicted pattern using normal entry procedures as described in ATC 10.5, and timing in the hold as described in ATC 10.6. ATC will use the following phraseology when clearing an aircraft holding at a fix that has a published holding pattern;

CLEARED TO THE (fix), HOLD (direction) AS PUBLISHED, EXPECT FURTHER CLEARANCE AT (time)

NOTE: The holding direction means the area in which the hold is to be completed in relation to the holding fix, e.g., east, northwest, etc. If a pattern is required that is different than that published, detailed holding instructions will be issued by ATC.

If a pilot is instructed to depart a fix that has a published hold, at a specified time, the pilot has the option to:

- a. proceed to the fix, then hold until the “depart fix” time specified;
- b. reduce speed to make good his/her “depart fix” time; or
- c. a combination of (a) and (b).

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

SECTION 11

11.1 REGULATION, REFERENCE DOCUMENTS AND GUIDANCE MATERIAL

11.1.1 Regulation

CAR 602.38 requires pilots of Canadian aircraft, when flying over the high seas, to comply with the applicable rules set out in ICAO Annex 2, *Rules of the Air*, and with the applicable regional supplementary procedures set out in ICAO Doc 7030.

11.1.2 North Atlantic (NAT) Documentation

- a. The following documents are applicable to operations in the NAT region:
 1. ICAO, Annex 2 – *Rules of the Air*;
 2. ICAO, Annex 11 – *Air Traffic Services*;
 3. ICAO, Doc 4444 – *Procedures for Air Navigation Services – Air Traffic Management* (PANS-ATM);
 4. ICAO, Doc 7030 – *Regional Supplementary Procedures* (NAT);
 5. ICAO, NAT Doc 001 – *NAT SPG Handbook*
 6. ICAO NAT Doc 006 – *Air Traffic Management Operational Contingency Plan – North Atlantic Region*;
 7. ICAO NAT Doc 007 – *North Atlantic Operations and Airspace Manual*; and
 8. *Gander Data Link Oceanic Clearance Delivery (OCD) Crew Procedures*.

11.2 GENERAL AVIATION AIRCRAFT

Canadian Aviation Regulation (CAR) 602.39 specifies the following:

No pilot-in-command of a single-engined aircraft, or of a multi-engined aircraft that would be unable to maintain flight in the event of the failure of any engine, shall commence a flight that will leave Canadian Domestic Airspace and enter airspace over the high seas unless

- a. the pilot-in-command holds a pilot licence endorsed with an instrument rating;
- b. the aircraft is equipped with
 1. the equipment referred to in section 605.18,
 2. a high frequency radio capable of transmitting and receiving on a minimum of two appropriate international air-ground general purpose frequencies, and
 3. hypothermia protection for each person on board; and
- c. the aircraft carries sufficient fuel to meet the requirements of section 602.88 and, in addition, carries contingency fuel equal to at least 10 percent of the fuel required pursuant to section 602.88 to complete the flight to the airport of destination.

CA 11 NORTH ATLANTIC (NAT) OPERATIONS

11.3 NORTH AMERICAN ROUTES (NAR)

The North American route (NAR) system interfaces with North Atlantic (NAT) oceanic, the oceanic transition area, and domestic airspace and is used by air traffic transiting the NAT. NARs consist of a series of pre-planned routes to and from established oceanic entry/exit points (OEP) and major identified airports throughout Canada and the United States.

NARs and their associated procedures are published in the Planning section of the *Canada Flight Supplement* (CFS) and in the Federal Aviation Administration's (FAA) *Airport Facility/Directory—Northeast*. (See also Jeppesen Enroute AT NARs section.)

11.4 GANDER OCEANIC TRANSITION AREA (GOTA)

The implementation of additional surveillance and communication sites along the north-east coast of Canada allowed for the provision of enhanced services and led to the creation of the Gander oceanic transition area (GOTA).

The lower limit of the GOTA is FL290; the upper limit is FL600. The GOTA is Class A controlled airspace.

The GOTA consists of airspace FL290 and above, from 6530N 060W, east to the Reykjavik area control center (ACC) boundary, south to 6330N 055W, south along 055W to the Gander domestic boundary, north along the Gander/Montreal domestic boundaries, north to the Edmonton boundary, and then back to the point of origin.

Figure 11.1 — Gander OCA

Surveillance services are provided by Gander ACC. The automatic dependence surveillance - contract/controller-pilot data link communications (ADS-C/CPDLC) log on address for aircraft in GOTA airspace is CDQX.

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

11.5 NORTH ATLANTIC (NAT) ORGANIZED TRACK SYSTEM (OTS)

Organized tracks are formulated and published in a North Atlantic (NAT) track message via the automatic fixed telecommunications network (AFTN) and sent to all interested operators. The daytime structure is published by Shanwick area control center (ACC) and the night-time structure is published by Gander ACC.

Flight levels are allocated for use within the organized track system (OTS) and in most cases, details of domestic entry and exit routings associated with individual tracks are provided in the NAT Track Message.

To permit an orderly change-over between successive OTSs, a period of several hours is interposed between the termination of one system and the commencement of the next. During these periods, operators are expected to file random routes or use the coordinates of a track in the system about to come into effect.

Eastbound traffic crossing 30°W at 1030 UTC or later and Westbound traffic crossing 30°W at 0000 UTC or later should plan to avoid the OTS at the published levels.

Further information on available flight level profiles can be found in paragraph 11.20.3.

11.6 FLIGHT RULES

Over the high seas, the lower limit of all North Atlantic (NAT) oceanic control areas (OCA) is FL055; there is no upper limit. Throughout the NAT Region, airspace at and above FL055 is Class A controlled airspace, and below FL055 is Class G uncontrolled airspace.

At or above FL060, flights shall be conducted under instrument flight rules (IFR) even when aircraft are not operating in instrument meteorological conditions (IMC).

Air traffic control (ATC) clearances to climb or descend while maintaining one's own separation and remaining in visual meteorological conditions (VMC) shall not be issued to aircraft.

11.7 FLIGHT PLANNING PROCEDURES

11.7.1 Routes

For eastbound and westbound traffic:

- a. South of 70°N, the planned tracks shall be defined by significant points formed by the intersection of half or whole degrees of latitude at each 10° of longitude (60°W, 50°W, 40°W). For flights operating north of 70°N, significant points are defined by the parallels of latitude expressed in degrees and minutes with longitudes at 20° intervals; the distance between significant points shall, as far as possible, not exceed one hour of flight time. Additional significant points should be established when required because of aircraft speed or the angle at which meridians are crossed. When the flight time between successive significant points is less than 30 minutes, one of the points may be omitted.
- b. Oceanic traffic transitioning through the GOTA from FL290 to FL600 shall flight plan an oceanic entry/exit point, a 050°W coordinate and a 040°W coordinate.

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

- c. The following OEPs are limited to flights conducted from FL290 and above: AVPUT, CLAVY, EMBOK, KETLA, LIBOR, MAXAR, NIFTY, PIDSO, RADUN, SAVRY, TOXIT, URTAK, VESMI, AVUTI, BOKTO, CUDDY, DORYY, and ENNSO.
- d. The following OEPs shall be flight planned by all aircraft entering or exiting Gander oceanic airspace, regardless of altitude: HOIST, IRLOK, JANJO, KODIK, LOMSI, MELDI, NEEKO, PELTU, RIKAL, SAXAN, TUDEP, UMESI, ALLRY, BUDAR, ELSIR, IBERG, JOOPY, MUSAK, NICSO, OMSAT, PORTI, RELIC, SUPRY, and RAFIN.

For northbound and southbound traffic, the planned tracks shall be defined by significant points formed by the intersection of whole degrees of longitude with parallels of latitude spaced at 5° (65°N, 60°N, 5°N).

For aircraft planning to fly within the OTS from the oceanic entry point to the oceanic exit point as detailed in the daily NAT track message, the track shall be defined in Item 15 of the flight plan by the abbreviation "NAT" followed by the code letter assigned to the track. Refer to paragraph 11.20.3.2 for more details on the OTS.

For eastbound NAT flights planning to operate on the OTS, the second and third route options should be indicated at the end of Item 18 of the flight plan. Those operators who do not have the capability to provide this information in Item 18 of the flight plan should send the information by separate AFTN message to Gander ACC (CYQXZQZX).

EXAMPLE:

- a. RMKS/ ... O2.X370 O3.V350 (Option 2 is Track X at FL370; Option 3 is Track V at FL350)
- b. RMKS/ ... O2.RS390 O3.Z370 (Option 2 is random track south at FL390; Option 3 is Track Z at FL370)

NOTE: In the preceding examples, Options 2 and 3 are indicated by the letter "O" and not the number zero.

ATS requires flights entering or exiting the Gander OCA to flight plan in accordance with the published NAT OTS or, if exiting by way of 58°N 050°W and south thereof, via the following OEPs (compulsory reporting points) and associated 050°W coordinates:

OEP	Coordinates	OEP	Coordinates
CUDDY or DORYY	58°N 050°W	UMESI	51°30'N 050°W
ENNSO	57°30'N 050°W	ALLRY	51°N 050°W
HOIST	57°N 050°W	BUDAR	50°30'N 050°W
IRLOK	56°30'N 050°W	ELSIR	50°N 050°W
JANJO	56°N 050°W	IBERG	49°30'N 050°W
KODIK	55°30'N 050°W	JOOPY	49°N 050°W
LOMSI	55°N 050°W	MUSAK	48°30'N 050°W

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

OEP	Coordinates	OEP	Coordinates
MELDI	54°30'N 050°W	NICSO	48°N 050°W
NEEKO	54°N 050°W	OMSAT	47°30'N 050°W
PELTU	53°30'N 050°W	PORTI	47°N 050°W
RIKAL	53°N 050°W	RELIC	46°30'N 050°W
SAXAN	52°30'N 050°W	SUPRY	46°N 050°W
TUDEP	52°N 050°W	RAFIN	45°N 050°W

ATS requires flights entering or exiting the New York OCA through CDA to flight plan over one of the following compulsory reporting points: NOVOK, JEBBY, BOBTU, or TALGO; or via ELERI or MUSPO, for flights arriving at or departing from Halifax airport (CYHZ). Eastbound flights that exit the New York OCA via CDA and subsequently enter the Gander OCA are required to flight plan in accordance with the published NAT OTS or over an oceanic entry point and a 050°W coordinate.

Flights exiting the New York OCA via BOBTU should contact Gander ACC five minutes prior to BOBTU on frequency 134.7 MHz. Operators should be aware that if the NAT OTS includes tracks that are at or south of SUPRY 46°N 050°W (or 46°N 050°W SUPRY), optimal flight levels and routes may not be available.

To facilitate effective coordination for flights entering or exiting the Gander domestic CTA and the New York OCA via 44°N 050°W or south thereof:

- a. Eastbound flights exiting the Gander domestic CTA directly into the New York OCA are required to flight plan via LOMPI direct JAROM direct TALGO, direct 44°N 050°W, or south thereof.
- b. Eastbound flights exiting the New York OCA directly into the Gander domestic CTA are required to flight plan via BOBTU.
 1. When the eastbound OTSs are anchored at RAFIN and/or TALGO, BOBTU will be unavailable for eastbound NAT traffic flight planning between FL300 and FL400, inclusive.
- c. Westbound flights exiting the New York OCA directly into the Gander domestic CTA are required to flight plan via BOBTU direct JAROM direct LOMPI.

NOTE: TALGO is not to be used for westbound flights.

ATS system parameters require all westbound flights transiting from the Gander OCA or the GOTA to the Montreal FIR/CTA to flight plan via 060°W below FL290 and via an oceanic entry point if operating from FL290 up to and including FL600, followed by both a boundary reporting point and then one of the following inland reporting points: LAKES, LOPVI, RODBO, JELCO, FEDDY, TEFFO, DUTUM, or BEZED. KENKI and IRBIM are not to be used as boundary reporting points. Flights operating from FL290 and above may flight plan a NAR to or from an oceanic entry point.

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

11.7.2 Airspeed

The TAS or Mach number is to be entered in Item 15 of the flight plan.

11.7.3 Altitude

The planned cruising level(s) for the oceanic portion of the flight should be included in Item 15 of the flight plan.

NOTE: Pilots planning to conduct a flight wholly or partly outside the OTS should indicate, in a flight plan, cruising level(s) appropriate to the direction of flight and in accordance with the flight levels as described in the NAT FLAS. Refer to paragraph 11.20.3 for more details on FLAS.

Requests for a suitable alternative flight level may be indicated in Item 18 of the flight plan.

11.7.4 Estimated Times

For NAT flights, the accumulated elapsed time only to the first oceanic FIR boundary (Gander accepts elapsed time to OEPs) is to be entered in Item 18 of the flight plan.

11.7.5 Aircraft Approval Status and Registration

For an aircraft certified as being in compliance with operations within the NAT HLA, the approval status (MNPS) shall be indicated in Item 10 by entering the letter "X". It is the pilot's responsibility to ensure that specific approval has been given for the NAT HLA operations. Refer to paragraph 11.11 for more information on MNPS in the NAT HLA.

For an aircraft certified as being in compliance with RVSM MASPS, RVSM approval shall be indicated in Item 10 by entering the letter "W". It is the pilot's responsibility to ensure that specific approval has been given for RVSM operations. Refer to paragraph 11.12 for more information on RVSM MASPS.

If the aircraft registration is not included in Item 7, it shall be indicated in Item 18.

11.7.6 Height Monitoring Unit (HMU)

An aircraft that requires HMU monitoring shall include in Item 18 of the flight plan the remarks "RMK/HMU FLT STU".

11.7.7 Filing

NAT operators shall forward all flight plans for eastbound NAT flights to the Canadian ACCs whose FIR or CTA the flights will traverse. These flight plans shall include the EET for each CTA boundary in Item 18 of the flight plan. The AFTN addresses for Canadian ACCs are:

- CZQXZQZX (Gander)
- CZQMZQZX (Moncton)
- CZULZQZX (Montréal)
- CZYZZQZX (Toronto)
- CZWGZQZX (Winnipeg)
- CZEGZQZX (Edmonton)

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

– CZVRZQZX (Vancouver)

Where possible, operators are to file eastbound NAT flight plans at least four hours prior to the ETA at the oceanic entry point specified in the flight plan.

11.8 PREFERRED ROUTE MESSAGE (PRM)

North Atlantic (NAT) operators shall send preferred route messages (PRMs) for eastbound flights to the following Gander Aeronautical Fixed Telecommunication Network (AFTN) addresses:

- a. CZQXZQZX (Gander ACC)
- b. CZULZQZX (Montréal ACC)

The following format is to be used for eastbound PRMs:

[PRIORITY] [DEST ADDRESS] [DEST ADDRESS] — [DATE TIME OF ORIGIN] [ORIGIN ADDRESS] [MESSAGE TYPE]-[COMPANY]-[EB]-[YYMMDD AT 030°W]-[(DEP/DEST) (INLAND FIX) (OEP) (OCA RPS) (LANDFALL) (LAST UK POINT) (NUMBER OF FLT 01-99)]

EXAMPLE:

FF CZQXZQZX

130502 KJFKSWRW

PRM-SWR-E-200113

CYUL/LSZH JOOPY 49/50 49/40 49/30 49/20 BEDRA NASBA 02

KJFK/LSZH PORTI 47/50 48/40 49/30 50/20 SOMAX ATSUR 03

NOTE 1: If there is no inland navigation fix (INF), the latitude crossing 80°W is to be used.

NOTE 2: PRMs for eastbound flights are to be sent no later than 1000 Coordinated Universal Time (UTC).

11.9 CLEARANCES

11.9.1 Oceanic Clearances

Pilots intending to operate aircraft in the Gander OCA should note the following:

- a. Clearances for VFR climb or descent will not be granted.
- b. The Mach number to be maintained will be specified.
- c. ATC will specify the full route details for aircraft cleared on a route other than an organized track or flight planned route. The pilot is to read back the full details of the clearance including the cleared track or details of the flight planned route.
- d. ATC will issue an abbreviated oceanic clearance to aircraft that will be operated along one of the NAT organized tracks. The abbreviated clearance will include the track letter, the flight level, and the Mach number or speed in knots to be maintained. The pilot is to read back the clearance including the TMI number. ATC will confirm the accuracy of the readback and the TMI number.

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

NOTE: The OTS is identified by a TMI number, which is determined by using the Julian calendar for the day on which the tracks are effective. (Refer to paragraph 11.20.3.2 for more information on OTS.) The TMI number is contained in the Remarks section on the NAT track message. Amendments to tracks that are already published are indicated by appending a letter to the Julian date, e.g. TMI 320A. A revised TMI will be issued for changes to:

- a. any track coordinate(s) including named points;*
- b. track published levels; or*
- c. named points within European routes west.*

A TMI revision will not be issued for changes to other items such as NARs.

- e. Whether received via data link or voice, the oceanic clearance to enter the Gander OCA has the following meaning:
1. The clearance is valid only within oceanic airspace, and details the route, altitude and speed at which the flight is to enter oceanic airspace;
 2. The flight crew is not immediately authorized to change the route, altitude or speed in order to comply with the oceanic clearance;
 3. The flight crew is required to obtain a subsequent clearance in order to comply with the oceanic clearance; and
 4. If unable to obtain a subsequent clearance, the flight crew should revert to the procedures for radio communications failure detailed in this section paragraph 11.18, the CFS and the NAT section of ICAO's *Regional Supplementary Procedures* (Doc 7030) in order to maneuver as necessary to comply with the oceanic clearance.

11.9.2 Domestic Clearances – NAT Westbound Traffic

Pilots proceeding westbound across the NAT and entering CDA within the Gander, Moncton and Montreal FIRs should comply with the following procedures:

- a. Flights whose oceanic clearance contains their flight planned oceanic exit point will not be issued enroute clearances upon entering the airspace and are to follow the flight planned route as cleared. Domestic enroute clearances will be issued:
 1. for flights that have been rerouted and exit oceanic airspace at a point other than the flight planned exit fix; or
 2. at a pilot's request for another routing; or
 3. if a flight plan has not been received by the ACC.
- b. Flights that have been rerouted from the flight planned route and enter CDA within 120 NM of the flight planned oceanic exit point can anticipate a clearance to regain the flight planned route by the INF unless the pilot requests a different routing. For flights entering CDA more than 120 NM from the flight planned oceanic exit point, a clearance will be issued following consultation with the pilot.

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

c. ATC will use the latest flight plan received before a flight departs. Subsequent changes to the flight plan route, including any changes received by the pilot from flight operations or dispatch, must be requested directly by the pilot on initial contact with the appropriate domestic ACC. Direct requests from flight operations or dispatch to ATC to reclear aircraft will only be considered under exceptional circumstances and are not an acceptable alternative to a pilot initiated request for reclearance.

d. Domestic reclearances by ATC may contain either the route specified in full detail or a NAR.

If an aircraft enters CDA via the Edmonton FIR, the onward domestic routing will have been established in coordination between the Reykjavik and Edmonton ACCs, and additional domestic clearance is not required. If there has been a change in route from the filed flight plan, clarification of the onward routing may be obtained from Edmonton ACC on request.

Westbound aircraft that have proceeded across the NAT and have entered the GOTA or CDA shall maintain the last oceanic Mach setting assigned by ATC:

- a. unless approval is obtained from ATC to make a change, or
- b. until the pilot receives an initial descent clearance approaching destination.

NOTE: Pilots should request changes to their oceanic Mach setting once communication has been established within the GOTA or CDA.

11.9.3 Oceanic Clearance Delivery

Unless otherwise advised by ATC, the following oceanic clearance delivery procedures are in effect daily between 2330 and 0730 UTC (DST 2230 and 0630 UTC) for all eastbound oceanic flights that transit the Gander domestic FIR/CTA:

- a. Clearance delivery frequencies are published daily in the Remarks section on the eastbound NAT track message. During published clearance delivery hours, pilots are to contact Gander Clearance Delivery on the frequency designated for their oceanic entry point. Pilots should contact Clearance Delivery when they are within 200 NM of the specified clearance delivery frequency location. In the event that contact cannot be established, pilots are to advise ATC on the assigned control frequency. The following frequencies and frequency locations will normally be used:

- Natashquan (YNA)
(50°11'N 61°47'W) – 135.45 MHz;
- Allan's Island
(46°50'N 55°47'W) – 128.45 MHz;
- Churchill Falls (UM)
(53°35'N 64°14'W) – 128.7 MHz;
- Stephenville (YJT)
(48°34'N 58°40'W) – 135.05 MHz;
- Sydney (YQY)

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

(46°09'N 60°03'W) – 119.42 MHz;

– Brevoort

(62°20'N 64°08'W) – 132.025 MHz;

– Kuujuaq (YVP)

(58°05'N 68°25'W) – 134.2 MHz.

- b. Operators who do not receive the NAT track message are to contact Gander Clearance Delivery when they are within 200 NM of the frequency location. In the event that contact cannot be established, pilots are to advise ATC on the assigned control frequency.

Pilots are to maintain a continuous listening watch on the assigned control sector frequency while obtaining the oceanic clearance.

Flights that are equipped to request and receive solicited electronic oceanic clearances are not required to contact Clearance Delivery if an electronic clearance is received and confirmed successfully. Confirmation is the receipt of the following message: CLA RECEIVED CLEARANCE CONFIRMED END OF MESSAGE.

If the above message is not received, data link oceanic clearances must be verified, either with Gander Clearance Delivery, during published hours, or on the control frequency, outside of published hours.

ATC will not normally advise pilots to contact Gander Clearance Delivery. There is no requirement for pilots to confirm receipt of an oceanic clearance (including a data link oceanic clearance) from Gander Clearance Delivery with the assigned control frequency. Due to frequency congestion on both the clearance delivery and sector control frequencies, pilots should refrain from unnecessary lengthy discussion with respect to oceanic clearances and procedures. Constructive comments and complaints should be processed postflight through the company operations.

Procedures and further information for flights intending to receive oceanic clearances via data link are published in *Gander Data Link Oceanic Clearance Delivery (OCD) Crew Procedures*.

11.10 POSITION REPORTS

11.10.1 Requirements

Unless otherwise requested by ATC, flights shall make position reports at all points contained in their oceanic clearance.

Position reports shall include the reported position, including the time it is reached, the current flight level (or passing flight level and final level if the aircraft is either climbing or descending), the next reporting point and estimated time, and the succeeding reporting point per the cleared route. If the estimated time over the next reporting point is found to be in error by three minutes or more, a revised estimated time shall be transmitted as soon as possible to the appropriate ATC unit. Revisions to forward estimates are not required for flights with established ADS-C contracts.

When making position reports, all times shall be expressed in hours and minutes UTC.

If an aircraft in the Gander OCA is unable to communicate with Gander oceanic, the pilot shall endeavor to relay position reports through:

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

- a. another oceanic control center with which communication has been established;
- b. another aircraft in the NAT region (when out of range of VHF ground stations, aircraft may use 123.45 MHz for air-to-air communications, including the relaying of position reports); or
- c. another aircraft on emergency frequencies 121.5 or 243.0 MHz, if no other means is available.

11.10.2 Communications With Air Traffic Control (ATC)

All aircraft operating in the Gander OCA must be capable of conducting two-way radio communication with ATC. The radio communication equipment shall consist of at least one HF and one other long-range communication system (HF, CPDLC, or SATVOICE). Carrying HF radio and the additional long-range communication system is mandatory, except for operations on routes covered by VHF facilities.

See CARs 602.38 and 602.39 for Canadian-registered aircraft or for aircraft entering the NAT via CDA.

For more details on equipage requirements in the NAT HLA, refer to ICAO Annex 2 *Rules of the Air* and to North Atlantic (NAT) Regional Supplementary Procedures in ICAO Doc 7030 *Regional Supplementary Procedures*, as well as national AIPs for the states concerned.

All flights operating in the Gander OCA should check in on international air-to-ground frequencies. Refer to *AIP Canada (ICAO)* ENR 7.1.10 for detailed procedures on making initial contact upon entering Gander OCA (not published herein).

**11.11 MINIMUM NAVIGATION PERFORMANCE SPECIFICATIONS (MNPS)
FOR OPERATIONS WITHIN THE NORTH ATLANTIC HIGH LEVEL
AIRSPACE (NAT HLA)**

11.11.1 General

All operators are to ensure that aircraft used to conduct flights within the NAT HLA have the minimum navigation equipment. For detailed requirements, refer to the following documents:

- a. International Civil Aviation Organization (ICAO) Doc 7030 — *Regional Supplementary Procedures (NAT)*;
- b. ICAO NAT Doc 001 — *NAT SPG Handbook*;
- c. ICAO NAT Doc 007 — *North Atlantic Operations and Airspace Manual*; and
- d. Parts VI and VII of the *Canadian Aviation Regulations (CARs)*.

Eastbound aircraft requesting an oceanic clearance from Gander ACC to enter the NAT HLA may be asked by ATC to confirm that they are approved for MNPS operations. Pilots/operators unable to provide such confirmation will be issued an oceanic clearance to operate their aircraft outside the NAT HLA (below FL285 or above FL420).

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

11.11.2 Aircraft Without Minimum Navigation Performance Specifications (MNPS) for the North-Atlantic High-Level Airspace (NAT HLA) Operations

An aircraft that does not meet the NAT HLA requirements may be allowed to operate in the NAT HLA if the following conditions are satisfied:

- a. The aircraft is being provided with ATS surveillance services;
- b. Direct controller-pilot VHF communication is maintained; and
- c. The aircraft has a certified installation of equipment providing it with the ability to navigate along the cleared track.

NOTE: Pilots operating aircraft in the NAT HLA under these provisions should familiarize themselves with NAT HLA operations and procedures. They should also have a current copy of the OTS message that is in effect for the time of their flight for situational awareness.

Aircraft that are not approved to operate in the NAT HLA and do not meet the above provisions may be cleared to climb or descend through the NAT HLA, traffic permitting.

11.12 REDUCED VERTICAL SEPARATION MINIMUM (RVSM) — MINIMUM AIRCRAFT SYSTEM PERFORMANCE SPECIFICATIONS (MASPS)

All operators of aircraft used to conduct flights within the North Atlantic High Level Airspace (NAT HLA) where reduced vertical separation minimum (RVSM) is applied are to ensure that they meet the minimum aircraft system performance specifications (MASPS). For detailed requirements, refer to the following publications:

- a. International Civil Aviation Organization (ICAO) Doc 7030 — *Regional Supplementary Procedures* (NAT);
- b. ICAO NAT Doc 001 — *NAT SPG Handbook*;
- c. ICAO NAT Doc 007 — *North Atlantic Operations and Airspace Manual*; and
- d. Parts VI and VII of the *Canadian Aviation Regulations* (CARs).

Eastbound aircraft requesting an oceanic clearance from Gander Area Control Center (ACC) to enter the NAT HLA at designated RVSM altitudes may be asked by Air Traffic Control (ATC) to confirm that they are approved for minimum navigation performance specifications (MNPS) and/or RVSM operations. Pilots/operators unable to provide such confirmation will be issued an oceanic clearance to operate their aircraft outside designated RVSM altitudes.

11.13 ADHERENCE TO MACH SETTING

While operating in the Gander oceanic control area (OCA) and Canadian Domestic Airspace (CDA), aircraft shall adhere to the Mach setting assigned by air traffic control (ATC) unless approval is obtained from ATC to make a change or until the pilot receives an initial descent clearance approaching destination. If it is essential to make an immediate temporary change in Mach setting (e.g., as a result of turbulence), ATC shall be notified as soon as possible that such a change has been made.

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

Pilots shall advise ATC at the time of the climb/descent request if it is not possible to maintain the last assigned Mach setting during enroute climbs and descents because of aircraft performance.

Fixed speed is no longer required for every flight crossing the North Atlantic (NAT). NAT operations without an assigned fixed speed (OWAFS) are now possible. Refer to *AIP Canada* ENR paragraph 7.1.11 for more details.

11.14 OPERATION OF TRANSPONDERS

Transponders must be operated at all times on Mode A or Mode C on Code 2000 while the aircraft is operated in the North Atlantic (NAT) region. However, the last air traffic control (ATC) assigned code must be retained for a period of 30 minutes after entry into NAT airspace unless otherwise directed by ATC.

NOTE: This procedure does not affect the use of the special purpose codes 7500, 7600, and 7700.

11.15 METEOROLOGICAL REPORTS

Aircraft must make, record, and report meteorological observations at each designated reporting point on a routine basis. However, aircraft cleared on an organized track should be required to make, record, and report meteorological observations only upon a specific request by air traffic control (ATC). The International Civil Aviation Organization (ICAO) air report (AIREP) form, as contained in Appendix 1 of the *Procedures for Air Navigation Services—Air Traffic Management* (Doc 4444), should be used for this purpose.

11.16 ALTITUDE REPORTS

Aircraft cleared for cruise climbs should report their level to the nearest 100 feet.

For all altitude changes, whether they are climbs or descents, pilots should report reaching the new level/cruising altitude to Air Traffic Control (ATC).

11.17 CONTINGENCY AND EMERGENCY PROCEDURES

11.17.1 In-Flight Contingencies

All pilots transiting the NAT should be thoroughly familiar with the in-flight contingency procedures for situations of rapid descent, turnback, diversion, and reduction of navigational capability.

In-flight contingency procedures are published in the following documents:

- a. International Civil Aviation Organization (ICAO) Doc 4444 — *Procedures for Air Navigation Services — Air Traffic Management*;
- b. ICAO Doc 7030 — *Regional Supplementary Procedures* (NAT);
- c. ICAO NAT Doc 001 — *NAT SPG Handbook*; and
- d. ICAO NAT Doc 007 — *North Atlantic Operations and Airspace Manual*, and
- e. NAT OPS Bulletins.

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

11.17.2 Contingency Procedures for Oceanic Traffic in the Event of an Evacuation of Gander Area Control Center (ACC)

1.17.2.1 AIRCRAFT PROCEDURES — Westbound			
a) Aircraft that do not receive an oceanic clearance			
i)	In the event that Gander ACC must be evacuated, only aircraft with received and acknowledged oceanic clearances will be permitted to transit the Gander OCA.		
ii)	If unable to obtain or acknowledge an oceanic clearance, flights should plan to re-route around the Gander OCA or land at an appropriate airport. Request the appropriate reclearance on the current frequency. Frequency congestion is likely.		
b) Aircraft that receive an acknowledged oceanic clearance			
i)	Aircraft operating with a received and acknowledged oceanic clearance should proceed in accordance with the clearance. Flights should not request changes in altitude, speed, or route except for flight safety reasons.		
ii)	Any flights involved in level changes should complete the maneuver as soon as possible in accordance with any restrictions provided with the clearance.		
c) Contact Procedures			
i)	Upon receipt of an emergency evacuation message, pilots are requested to broadcast to other flights on 121.5, 243.0, and 123.45. A listening watch on these frequencies and the current frequency should be maintained until the flight exits the Gander OCA and FIR.		
ii)	All flights within the Gander OCA should transmit position reports on any available HF or VHF frequency to Shanwick Radio either directly or through another agency or flight.		
iii)	Flights should establish communication with the next agency at the earliest opportunity, stating their current position, cleared flight level, next position and estimate, and subsequent position. This also applies to flights using automated position reports (ADS/FMC) because those reports may not have been received by the next agency.		
iv)	Flights within the Gander OCA should initially establish contact with Shanwick Radio. Flights within the Gander FIR should contact Montreal Center or Moncton Center, depending on their oceanic exit point as described in subparagraph vii) below. Flights about to exit the Gander OCA into the New York OCA, the Reykjavik Oceanic CTA, the Santa Maria OCA, or the Nuuk FIR should contact New York Radio, Iceland Radio, Santa Maria Radio, or Nuuk Radio as appropriate.		
v)	If unable to establish radio contact, flights may use SATVOICE to provide position reports.		
	Oceanic Center	Public Switched Telephone Network (PTSN) Number	Short Code
	Gander Shift Manager	001-709-651-5207	N/A

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

1.17.2.1 AIRCRAFT PROCEDURES — Westbound

vi)	Aircraft may request that their flight dispatch offices forward position reports, if these aircraft are sending position reports to multiple ATS Units or if they are otherwise unable to forward position reports.																																																																						
vii)	Based on where they exit oceanic airspace, flights shall proceed in accordance with the following table until communication is established with the next agency and this agency issues a reclearance. For flights operating at FL290 and above: <table> <tr> <th>Flight is routed over:</th><th>The flight shall proceed to:</th><th>Next control agency and frequency:</th></tr> <tr><td>AVPUT</td><td>NALDI DUTUM</td><td>Montreal ACC 134.85</td></tr> <tr><td>CLAVY</td><td>KAGLY TEFFO</td><td>Montreal ACC 134.85</td></tr> <tr><td>EMBOK</td><td>IKMAN FEDDY</td><td>Montreal ACC 134.85</td></tr> <tr><td>KETLA</td><td>GRIBS JELCO</td><td>Montreal ACC 134.80</td></tr> <tr><td>LIBOR</td><td>6101N 06241W</td><td>Montreal ACC 134.80</td></tr> <tr><td>MAXAR</td><td>MIBNO RODBO</td><td>Montreal ACC 133.20</td></tr> <tr><td>NIFTY</td><td>MUSLO</td><td>Montreal ACC 133.20</td></tr> <tr><td>PIDSO</td><td>PEPKI LOPVI</td><td>Montreal ACC 135.80</td></tr> <tr><td>RADUN</td><td>SINGA</td><td>Montreal ACC 135.80</td></tr> <tr><td>SAVRY</td><td>LAKES MCKEE</td><td>Montreal ACC 132.45</td></tr> <tr><td>TOXIT</td><td>UDMAR</td><td>Montreal ACC 132.45</td></tr> <tr><td>URTAK</td><td>TEALS VANSI</td><td>Montreal ACC 119.40</td></tr> <tr><td>VESMI</td><td>ALSOP</td><td>Montreal ACC 119.40</td></tr> <tr><td>AVUTI</td><td>YKL ROUND</td><td>Montreal ACC 119.40</td></tr> <tr><td>BOKTO</td><td>VOKET DUVBI</td><td>Montreal ACC 119.40</td></tr> <tr><td>CUDDY</td><td>YWK MT</td><td>Montreal ACC 132.90@63W</td></tr> <tr><td>DORYY</td><td>YBC ANCER</td><td>Moncton ACC 132.95</td></tr> <tr><td>HOIST</td><td>YRI</td><td>Moncton ACC 118.875</td></tr> <tr><td>IRLOK</td><td>5031N 06500W</td><td>Moncton ACC 118.875</td></tr> <tr><td>JANJO</td><td>CEFOU</td><td>Moncton ACC 118.875</td></tr> <tr><td>KODIK</td><td>4941N 06500W</td><td>Moncton ACC 132.52</td></tr> <tr><td>LOMSI</td><td>QUBIS</td><td>Moncton ACC 132.52</td></tr> </table>		Flight is routed over:	The flight shall proceed to:	Next control agency and frequency:	AVPUT	NALDI DUTUM	Montreal ACC 134.85	CLAVY	KAGLY TEFFO	Montreal ACC 134.85	EMBOK	IKMAN FEDDY	Montreal ACC 134.85	KETLA	GRIBS JELCO	Montreal ACC 134.80	LIBOR	6101N 06241W	Montreal ACC 134.80	MAXAR	MIBNO RODBO	Montreal ACC 133.20	NIFTY	MUSLO	Montreal ACC 133.20	PIDSO	PEPKI LOPVI	Montreal ACC 135.80	RADUN	SINGA	Montreal ACC 135.80	SAVRY	LAKES MCKEE	Montreal ACC 132.45	TOXIT	UDMAR	Montreal ACC 132.45	URTAK	TEALS VANSI	Montreal ACC 119.40	VESMI	ALSOP	Montreal ACC 119.40	AVUTI	YKL ROUND	Montreal ACC 119.40	BOKTO	VOKET DUVBI	Montreal ACC 119.40	CUDDY	YWK MT	Montreal ACC 132.90@63W	DORYY	YBC ANCER	Moncton ACC 132.95	HOIST	YRI	Moncton ACC 118.875	IRLOK	5031N 06500W	Moncton ACC 118.875	JANJO	CEFOU	Moncton ACC 118.875	KODIK	4941N 06500W	Moncton ACC 132.52	LOMSI	QUBIS	Moncton ACC 132.52

1.17.2.2 AIRCRAFT PROCEDURES — Eastbound

a) Aircraft that do not receive an oceanic clearance

- | | |
|-----|---|
| i) | In the event that Gander ACC must be evacuated, only aircraft with received and acknowledged oceanic clearances will be permitted to transit the Gander OCA. |
| ii) | If unable to obtain or acknowledge an oceanic clearance, flights should plan to re-route around the Gander OCA or land at an appropriate airport. Flights may be required to re-route around the Gander FIR as well. Flights should request the appropriate re-clearance from Montreal or Moncton Center. Frequency congestion is likely. |

b) Aircraft that receive an acknowledged oceanic clearance

- | | |
|------|---|
| i) | Aircraft operating with a received and acknowledged oceanic clearance should proceed in accordance with the clearance. Flights should not request changes in altitude, speed, or route except for reasons of flight safety or to comply with the oceanic clearance. |
| ii) | Flights west of 50°W longitude should contact either Montreal or Moncton Center, depending on which of the two was the previous agency, using the previous assigned frequency. |
| iii) | If a level change is required to comply with the oceanic clearance, the flight should request clearance from Montreal or Moncton Center. If unable to obtain an ATC clearance, the aircraft should climb or descend so as to cross the oceanic entry point at the cleared oceanic flight level. |

- iv) The Eastbound Organized Track System will be extended to begin at fixes on or near the western boundary between the Gander FIR and the Moncton and Montreal FIRs as follows:

v)	Flights at or east of 50°W longitude should initially contact Shanwick Radio. Flights about to exit the Gander OCA should contact New York Radio, Santa Maria Radio, Iceland Radio, or Nuuk Radio as appropriate. The following information should be provided: a. call sign; b. current position; c. current flight level and cleared oceanic flight level (if different from the current level); d. assigned Mach or speed; e. next waypoint and estimate; and f. subsequent waypoint.		
vi)	The following communications procedures have been developed in accordance with the Traffic Information Broadcast by Aircraft (TIBA) procedures recommended by ICAO Annex 11 — <i>Air Traffic Services</i>, Attachment C. Unless otherwise instructed by Moncton or Montreal Center, aircraft should apply these procedures when completing an altitude change to comply with the oceanic clearance. At least 3 minutes prior to initiating a climb or descent, the flight should broadcast the following on the last assigned frequency, 121.5, 243.0, or 123.45: ALL STATIONS (call sign) (direction) DIRECT FROM (landfall fix) TO (oceanic entry point) LEAVING FLIGHT LEVEL (number) FOR FLIGHT LEVEL (number) AT (distance) (direction) FROM (oceanic entry point) AT (time) When the level change begins, the flight should make the following broadcast:		

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

1.17.2.2 AIRCRAFT PROCEDURES — Eastbound

	ALL STATIONS (call sign) (direction) DIRECT FROM (landfall fix) TO (oceanic entry point) LEAVING FLIGHT LEVEL (number) NOW FOR FLIGHT LEVEL (number) When level, the flight should make the following broadcast: ALL STATIONS (call sign) MAINTAINING FLIGHT LEVEL (number)
vii)	When ADS-equipped flights are notified of a Gander evacuation, they must revert to voice position reporting until they are either clear of Gander OCA or notified otherwise. Pilots should note that they may be asked to log on to EGGX when within the Gander OCA; they should not initiate this action until instructed to do so.

11.18 COMMUNICATIONS FAILURE — NORTH ATLANTIC (NAT) TRAFFIC

The following procedures are intended to provide general guidance for North Atlantic (NAT) aircraft experiencing a communications failure. It is impossible to provide guidance for all possible situations associated with a communications failure.

11.18.1 General

If the aircraft is so equipped, a pilot experiencing a two-way radio communications failure shall operate the transponder in Mode C and squawk Code 7600.

The pilot shall also attempt to contact any ATC facility, inform them of the difficulty, and request that information be relayed to the ATC facility.

11.18.2 Communications Failure Prior to Entering the North Atlantic (NAT) Oceanic Airspace

If operating with a received and acknowledged oceanic clearance, the pilot should enter oceanic airspace at the cleared oceanic entry point, flight level and speed, and proceed in accordance with the received and acknowledged oceanic clearance. Any flight level or speed changes required to comply with the oceanic clearance should be completed within the vicinity of the oceanic entry point. The cleared oceanic flight level is the flight level contained in the oceanic clearance.

If operating without a received and acknowledged oceanic clearance, the pilot should enter oceanic airspace at the first oceanic entry point, level and speed, as contained in the filed flight plan and proceed via the filed flight plan route to landfall. The first oceanic level and speed should be maintained to landfall.

CA 11

NORTH ATLANTIC (NAT) OPERATIONS

11.18.3 Communications Failure Prior to Exiting the North Atlantic (NAT) Oceanic Airspace

If the oceanic clearance includes the flight planned oceanic exit point, the pilot should proceed in accordance with the last received and acknowledged oceanic clearance, including flight level and speed, to the last specified oceanic exit point. The pilot should continue on the flight plan route and, after passing the last specified oceanic exit point, conform to the relevant state procedures and regulations.

If cleared on a route that contains an oceanic exit point other than the one contained in the flight plan, the pilot should proceed in accordance with the last received and acknowledged oceanic clearance, including flight level and speed, to the last specified oceanic route point. After passing this point, the pilot should conform to the relevant state procedures and regulations, rejoining the filed flight plan route by proceeding, via published ATS routes where possible, to the next significant point west of the last oceanic route point contained in the filed flight plan.

11.19 NORTH ATLANTIC HIGH LEVEL AIRSPACE (NAT HLA)

11.19.1 General

The NAT HLA is that volume of airspace between FL285 and FL420 within the OCAs of Bodo Oceanic, Gander Oceanic, New York Oceanic East, Reykjavik, Santa Maria, and Shanwick excluding the Brest Oceanic Transition Area (BOTA) and the Shannon Oceanic Transition Area (SOTA).

Operators of Canadian-registered aircraft intending to fly in the NAT HLA will be required to show that they meet all the applicable standards. Information on the measures necessary to gain approval may be obtained from the following:

NOTE: Prior to February 2016, NAT HLA was referred to as minimum navigation performance specifications (MNPS) airspace. As of January 2022, ICAO is removing all references to MNPS in the documentation, starting with NAT Doc 007. The Canadian Aviation Regulations (CARs) still refer to MNPS airspace and MNPS requirements. Therefore, the replacement of MNPS with NAT HLA is a transition in progress, which means both terms can be considered interchangeable until the removal is complete. Furthermore, Filing X in Field 10a of the flight plan is still required to indicate authorization to operate in the NAT HLA.

Figure 11.2 — NAT HLA Between FL285 and FL420

11.19.2 Time Keeping Procedures

Prior to entry into NAT HLA, the time reference system(s) to be used during the flight for calculation of waypoint ETAs and waypoint ATAs should be synchronized to UTC. All ETAs and ATAs passed to ATC should be based on a time reference that has been synchronized to UTC or equivalent. Acceptable sources of UTC include the following:

- The United States National Institute of Standards and Technology (NIST) HF radio station near Fort Collins, Colo., (call sign WWV), which operates 24 hr a day on 2500, 5000, 10,000, 15,000, 20,000 kHz (AM/SSB) and announces UTC time at the top of each minute.
- Approved (TSO-C129) GPS equipment on board (corrected to UTC) that allows pilots to access UTC time 24 hr a day.
- The National Research Council of Canada HF radio station in Ottawa (call sign CHU), which is available 24 hr a day on 3330, 7850, and 14,670 kHz (SSB) and makes, in the final ten-

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

second period of each minute, a bilingual station identification and time announcement in UTC.

- d. The British Broadcasting Corporation (BBC), which transmits the Greenwich time signal once every hour on a number of domestic and worldwide frequencies.
- e. Any other source shown to the State of Registry or State of Operator (as appropriate) to be an equivalent source of UTC.

11.19.3 Provisions for Partial Loss of Navigation Capability

If an aircraft suffers partial loss of navigation capability (in which only one long-range navigation system is serviceable) prior to entry into oceanic airspace, the following routes should be considered:

- a. STN – 6000N 01000W (ATSIX) – 6100N 01234W – ALDAN KFV;
- b. BEN – 6100N 01000W (RATSU) – ALDAN – KFV;
- c. MAC – BEL – GOW – SHA – 5700N 01000W (GOMUP) – 6000N 01500W – 6100N 01630W BREKI KFV;
- d. KFV – SOPEN – DA – SF – YFB;
- e. KFV – EPENI – 6300N 03000W – 6100N 04000W – OZN;
- f. OZN – 5900N 05000W – AVUTI (FL290-FL600) – PRAWN – YDP;
- g. OZN – 5900N 05000W – CUDDY (FL290-FL600) – PORGY;
- h. OZN – 5800N 05000W – HOIST – YYR;
- i. SF – 6700N 06000W (DARUB) – YXP; and
- j. RE – 6930N 02240W – CP.

These routes are subject to the following conditions:

- a. sufficient navigation capability remains to meet the requirements for the NAT HLA and the requirements in *ICAO Annex 6, Part I, section 7.3* and *ICAO Annex 6, Part II, section 3.7.2* can be met by relying on the use of short-range NAVAIDs.
- b. a revised flight plan is filed with the appropriate ATS unit; and
- c. an ATC clearance is obtained.

NOTE 1: A revised oceanic clearance will be issued after co-ordination between all oceanic ACCs concerned.

NOTE 2: If the OTS extends to the northern part of the NAT Region, the aircraft concerned may be required to accept a lower than optimum flight level in its revised oceanic clearance, especially during peak traffic periods.

NOTE 3: This guidance material does not relieve the pilot from the requirement to take the best possible course of action in the light of prevailing circumstances

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

11.19.4 Special Routes for Aircraft Fitted with a Single Long-Range Navigation System

In order to be considered capable of operating along the routes listed below, aircraft must have state approval to operate in NAT HLA, be equipped with normal short-range navigation equipment (VOR/DME, ADF) and have at least one fully operational set of one of the following navigation equipment:

- a. DOPPLER with computer;
- b. INS;
- c. GPS approved in accordance with the requirements specified in TSO C-129 (Class A1, A2, B1, B2, C1, or C2); or
- d. FMS or IRS.

The aforementioned routes are known as Blue Spruce routes and are as follows:

- a. STN or BEN – 60N 010W (ATSIX) – 61N 01234W – ALDAN – KJV (HF required on this route);
- b. STN or BEN – 61N 010W (RATSU) – ALDAN – KJV (VHF coverage exists and, subject to prior coordination with Scottish Airways and Prestwick [Shanwick OAC], this route may be used by non-HF equipped aircraft);
- c. MAC, BEL, GOW, SGA – 57N 010W (GOMUP) – 60N 015W – 61N 01630W – BREKI KJV (HF required on this route);
- d. Tango Nine (T9) – 483554N 0090000W (LASNO) – 45N 009W (BEGAS) – STG (HF required on this route);
- e. Tango Sixteen (T16) – 485020N 0120000W (OMOKO) – 4500N 01600W (GONAN) – 4000N 01600W – NAVIX (HF required on this route);
- f. Tango Two One Three (T213) – 484343N 0102950W (TAMEL) – 4500N 01300W (BERUX) (HF required on this route);
- g. KJV – SOPEN – DA – SF – YFB;
- h. KJV – EPENI – 6300N 03000W – 6100N 04000W – OZN;
 - i. OZN – 5900N 05000W – AVUTI (FL290-FL600) – PRAWN – YDP;
 - j. OZN – 5900N 05000W – CUDDY (FL290-FL600) – PORGY;
 - k. OZN – 5800N 05000W – HOIST – YYR;
 - l. SF – 6700N 06000W (DARUB) – YXP;
- m. RE – 6930N 02240W – CP;
- n. Funchal/Porto Santo – Santa Maria/Ponta Delgada; and
- o. Lisboa Porto Faro – Ponta Delgada/Santa Maria/Lajes.

CA 11 NORTH ATLANTIC (NAT) OPERATIONS

The following routes are additional routes within the NAT HLA between Iceland, Greenland and Canada:

- a. SF – 6700N 06000W (DARUB) – YXP;
- b. RE – 6930N 02240W – CP.

11.19.5 Aircraft Without Minimum Navigation Performance Specifications (MNPS) Capability

An aircraft that does not meet the NAT HLA requirements may be allowed to operate in the NAT HLA if the following conditions are satisfied:

- a. The aircraft is being provided with ATS surveillance services;
- b. Direct controller-pilot VHF communication is maintained; and
- c. The aircraft has a certified installation of equipment providing it with the ability to navigate along the cleared track.

NOTE: Pilots operating aircraft in the NAT HLA under these provisions should familiarize themselves with NAT HLA operations and procedures. They should also have a current copy of the OTS message that is in effect for the time of their flight for situational awareness.

Aircraft that are not approved to operate in the NAT HLA and do not meet the above provisions may be cleared to climb or descend through the NAT HLA, traffic permitting.

11.19.6 Monitoring of Gross Navigation Errors

In order to ensure that the required navigation standards are being observed within the NAT HLA, a continuous monitoring of the navigation accuracy of aircraft in this airspace takes place using surveillance systems in Canada, Ireland, France, Iceland, and the United Kingdom. In cases of a gross navigation error, the pilot will normally be notified by the ATC unit observing the error. The subsequent investigation to determine the error will involve the ATC unit, the operator, and the State of Registry.

If there is a serious increase in the number of large errors, it may become necessary to increase separation standards until remedial action has been determined. Alternatively, if rapid corrective action cannot be achieved, it may be necessary for the State of Registry or the State of the Operator to temporarily exclude offending aircraft types or operators from the NAT HLA.

11.20 NORTH ATLANTIC (NAT) REDUCED VERTICAL SEPARATION MINIMUM (RVSM)

11.20.1 Geographic Boundaries

In the NAT, RVSM airspace is airspace within the geographic extent of the NAT Region from FL290 to FL410 inclusive.

11.20.2 Reduced Vertical Separation Minimum (RVSM) Details and Procedures

For RVSM details and procedures applicable to both the NAT and Canadian Domestic Airspace see ATC — ATC SPECIAL PROCEDURES — Reduced Vertical Separation Minimum (RVSM).

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

11.20.3 Flight Level Allocation Scheme (FLAS)

As with procedures in CDA, aircraft flight planning in oceanic airspace should normally plan for a flight level appropriate to the direction of flight, particularly when they are operating outside of the OTS structure and valid times.

In an effort to provide efficient and economic profiles, NAT ANSPs, through consultation, have designed the FLAS.

The FLAS standardizes flight levels available for traffic routing on and outside of the OTS as well as during transition times (times between valid OTS).

Aircraft operators are advised to flight plan using the flight levels specified in this document, relative to their particular flight(s).

11.20.3.1 Procedures

FLAS procedures entail:

- a. the establishment of flight level profiles normally available during OTS valid times;
- b. the establishment of flight level profiles during OTS changeover periods;
- c. the establishment of a night datum line, with the area south of the line reserved principally for traffic originating in New York/Santa Maria; and
- d. the establishment of a north datum line, with the area on or north of the line reserved for late-running westbound traffic from Reykjavik to Gander.

11.20.3.2 Organized Track System (OTS)

a. Westbound

1. The westbound OTS message is designed and published by Shanwick daily.
2. The most northerly track of a day OTS is designated as NAT Track Alpha; the adjacent track to the south, as NAT Track Bravo; and so on.
3. The valid times are 1130 to 1900 UTC at 30°W.
4. The flight level profiles normally published are FL310 to FL390 inclusive
5. Tracks that landfall at or north of CUDDY FL340 will not be published.
 - FL340 is omitted from these tracks to allow profiles for aircraft originating in the Reykjavik OCA.

b. Eastbound

1. The eastbound OTS message is designed and published by Gander daily.
2. The most southerly track is designated as Track Zulu; the adjacent track to the north as Track Yankee; and so on.
3. The valid times are 0100 to 0800 UTC at 30°W.
4. The flight level profiles normally published are FL310 to FL400 inclusive.

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

- FL310 is available on New York tracks only.
- 5. Eastbound traffic routing, south of both the night datum line and the main OTS, should flight plan using FL310, FL340, FL360, or FL380.
- 6. New York Tracks entering Shanwick OCA that cross, or route south of, the night datum line may be any combination of FL310, FL340, FL360, or FL380, or as otherwise agreed between Santa Maria and New York. Additional levels will be allocated to New York Tracks if the core OTS is located in that area.

NOTE: For this procedure “New York Tracks” are any eastbound OTS Tracks that originate in the New York area and enter Gander or Shanwick OCAs.

11.20.3.3 Organized Track System (OTS) Changeover Periods

a. Basic Principles:

1. The time period between the expiration of one OTS and the commencement of another set is known as the OTS changeover period.
2. All times relate to 030°W.
3. OTS changeover rules apply from 0801 to 1129 UTC and from 1901 to 0059 UTC.
4. During these times, flight levels shall be applied in accordance with the direction of flight except as stated below.

b. Guidelines

1. Westbound traffic crossing 030°W from 2230 to 0059 UTC:
 - Remain clear of the incoming OTS; and
 - Do not plan delegated ODLs (FL340 and FL380).
 - After 2230 UTC, the published OTS flight levels and ODLs are released to Gander for the use of eastbound traffic.
2. Eastbound traffic crossing 030°W from 1000 to 1129 UTC:
 - Remain clear of the incoming OTS at FL350; and
 - Do not plan the delegated ODL (FL330).
 - After 1000 UTC, the OTS (at FL330 and FL350) and ODL (FL330) are released to Shanwick for the use of westbound traffic.
3. Eastbound traffic crossing 30°W from 1030 to 1129 UTC at FL370 and FL390:
 - Remain clear of the incoming OTS.
 - After 1030 UTC, the OTS (at FL370 and FL390) is released to Shanwick for the use of westbound traffic.
4. At the end of westbound (daytime) OTS:

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

- Westbound aircraft crossing 030°W until 1900 UTC at the ODL (FL330) or on the OTS shall have priority over eastbound aircraft.

- During the westbound OTS hours of validity, Gander delegates FL330 to Shanwick for use by westbound traffic.

5. At the end of eastbound (night-time) OTS:

- Eastbound aircraft crossing 030°W until 0800 UTC at the ODLs (FL340 and FL380) or on the OTS shall have priority over westbound aircraft. The table below provides a summary:

OTS Changeover Periods

Level	Time (UTC)	Direction
FL430	24 hours	Westbound May be flight planned as eastbound by non-RVSM aircraft.
FL410	24 hours	Eastbound
FL400	0801–2229 2230–0059 0100–0800	Westbound Westbound (avoiding OTS) Eastbound OTS (subject to westbounds) Westbound (avoiding OTS) Eastbound (OTS)
FL390	1901–1029 1030–1129 1130–1900	Eastbound Eastbound (avoiding OTS) Westbound OTS (subject to eastbounds) Eastbound (avoiding OTS) Westbound (OTS)
FL380	0300–0700 0801–2229 2230–0059 0100–0800	Westbound (ODL, on and to the North of the North datum line) Westbound Eastbound (subject to westbounds) Eastbound (OTS and ODL)
FL370	1901–1029 1030–1129	Eastbound Eastbound (avoiding OTS) Westbound OTS (subject to eastbounds)

**CA 11
NORTH ATLANTIC (NAT) OPERATIONS**

OTS Changeover Periods (continued)

Level	Time (UTC)	Direction
	1130–1900	Eastbound (avoiding OTS) Westbound (OTS)
FL360	0801–2229 2230–0059 0100–0800	Westbound Westbound (avoiding OTS) Eastbound (subject to westbounds) Westbound (avoiding OTS) Eastbound (OTS)
FL350	1901–0959 1000–1129 1130–2000	Eastbound Eastbound (avoiding OTS) Westbound OTS (subject to eastbounds) Eastbound (avoiding OTS) Westbound (OTS)
FL340	0801–2229 2230–0059 0100–0800	Westbound Eastbound (subject to westbounds) Eastbound OTS (subject to westbounds) Eastbound (OTS and ODL)
FL330	1901–0959 1000–1129 1130–1900	Eastbound Westbound (subject to eastbounds) Westbound (OTS and ODL)
FL320	0801–2229 2230–0059 0100–0800	Westbound Westbound (avoiding OTS) Eastbound OTS (subject to westbounds) Westbound (avoiding OTS) Eastbound (OTS)
FL310	24 hours	Westbound (ODL)
FL300	24 hours	Westbound
FL290	24 hours	Eastbound

11.20.3.4 *Night Datum Line*

During the eastbound OTS hours of validity, a static datum line, known as the night datum line, is established with the following coordinates:

CA 11 NORTH ATLANTIC (NAT) OPERATIONS

45°N 030°W – 49°N 020°W – SOMAX – ATSUR

FL340 and FL380 are delegated to Gander for eastbound traffic on and to the north of the night datum line.

FL340 will not be used for Gander eastbound traffic to the south of the night datum line.

FL380 will not be used for Gander eastbound traffic to the south of either the night datum line or the eastbound OTS, whichever is further south.

Figure 11.3 — Night Datum Line

11.20.3.5 North Datum Line

Between 0300 and 0700 UTC, a static datum line, known as the north datum line, is established with the following coordinates:

URTA – 60°N 050°W – 62°N 040°W – 63°N 030°W

On and to the north of the north datum line, FL380 is delegated to Reykjavik for use by west-bound traffic.

CA 11 NORTH ATLANTIC (NAT) OPERATIONS

In the event of a high volume of north random flights or OTS tracks, the north datum line may be suspended to accommodate the anticipated eastbound traffic demand.

Figure 11.4 — North Datum Line

11.20.4 North Atlantic (NAT) Reduced Vertical Separation Minimum (RVSM) Aircraft Approvals

Operators of Canadian-registered aircraft intending to fly in NAT MNPS/RVSM airspace will be required to show that they meet all of the applicable standards. Further information on the measures necessary to gain approval may be obtained from the following:

NORTH ATLANTIC (NAT) OPERATIONS

Fax: +44 1292 692754

E-Mail: natcma@nats.co.uk

Information on the responsibilities of the CMA and the procedures applicable to it are contained in ICAO, NAT Doc 001 — *NAT SPG Handbook*, available at the following address: <http://www.icao.int/EURNAT/Pages/EUR-and-NAT-Document.aspx>.

11.20.6 Data Link Mandate (DLM) Airspace

11.20.6.1 General Information

The objectives of the NAT Data Link Mandate are to enhance communication, surveillance, and ATC intervention capabilities in the NAT region. ADS-C provides conformance monitoring of aircraft adherence to cleared routes and flight levels, significantly enhancing safety. ADS-C also facilitates SAR operations, including the capability to locate the site of an accident in oceanic airspace. CPDLC substantially improves air-ground communications capability, and therefore, controller intervention capability.

11.20.6.2 Data Link Mandate (DLM) Flight Levels

DLM airspace encompasses FL290 to FL410, inclusive, throughout the NAT region.

11.20.6.3 Flights Permitted to Operate Within NAT DLM Airspace

The following flights are permitted in NAT DLM airspace:

- a. Flights equipped with and prepared to operate FANS 1/A (or equivalent) CPDLC and ADS-C data link systems (see ICAO Doc 7030 3.3.2 and 5.4.2);
 1. The appropriate equipage to be indicated in Item 10 of the ICAO flight plan is:
 - (a) D1; and
 - (b) One of the following: J2, J5, or J7.
- b. Non-equipped flights that file STS/FFR, HOSP, HUM, MEDEVAC, SAR, or STATE in item 18 of the flight plan.

NOTE: Such flights may not receive an ATC clearance that matches flight-planned requests, depending on tactical situations.

11.20.6.4 Operational Policies

Non-equipped aircraft may request to climb or descend through NAT DLM airspace. Such requests will be considered on a tactical basis.

Altitude reservation requests will be considered on a case-by-case basis irrespective of the equipage status of the requesting aircraft.

11.20.6.5 Equipment Failure of Either ADS-C or CPLDC Systems

- a. Prior to departure:
 1. Resubmit the flight plan to remain clear of NAT DLM airspace.

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

- b. After departure but prior to entering DLM airspace:
 - 1. Notify ATC prior to entering DLM airspace.
 - 2. Requests to operate in DLM airspace will be considered on a tactical basis.
- c. After entering NAT DLM airspace:
 - 1. Notify ATC immediately.
 - 2. Tactical consideration will be given to allow the flight to continue in NAT DLM airspace. Flights may be required to exit NAT DLM airspace if this is warranted due to traffic.

11.20.7 Height Monitoring

For the NAT, height-monitoring is carried out using a hybrid system comprising a fixed ground-based HMU and a GPS-based monitoring system comprising portable GMUs.

11.20.8 Height Monitoring Unit (HMU)

The HMU site is located at Strumble, UK, 15 NM east of the Strumble VOR/DME (STU) beneath Upper ATS UG1 at coordinates 51°56'00"N 04°40'00"W. (See Figure 11.6.)

The coverage area for the Strumble HMU is a 13.8 NM radius circle from FL290 to FL410 inclusive.

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

Figure 11.6 — Strumble HMU

11.20.8.1 Pre-flight Procedures

Operators proposing to divert from an optimum route in order to fly over the Strumble HMU should check the HMU status at +44 1292 692760 (UK) for serviceability information. Every effort will be made to ensure that the promulgated information is accurate, but operators should note that the equipment may become unserviceable at short notice.

Pilots of aircraft that must be monitored should flight plan their route over STU. Item 18 of the flight plan must include both the aircraft registration (if not included in Item 7) and the remarks "RMK/HMU FLT STU".

CA 11

NORTH ATLANTIC (NAT) OPERATIONS

11.20.8.2 In-flight Procedures

Prior to an overflight of the Strumble HMU, pilots are requested to transmit “for HMU flight” to London Control on initial contact and, if they are not RVSM approved, a request for a level between FL290 and FL410 (inclusive) should be made. The controller will endeavour to allow the aircraft to route through the HMU coverage area in straight and level flight, if operational requirements so permit.

11.20.8.3 Post-Flight Procedures

ATC is not aware whether an aircraft has been successfully monitored by the HMU. Operators wishing to ascertain this information may send a fax to the NAT CMA or complete and submit the HMU request form, available at <http://natacma.com/height-monitoring-2/strumble-hmu/>. Please note that operators are encouraged to use the NAT CMA Web site.

Operator queries for specific overflights may be made to the NAT CMA. Such queries should include the Mode S or A codes and approximate time of overflight.

11.21 STRATEGIC LATERAL OFFSET PROCEDURE (SLOP) IN THE NORTH ATLANTIC (NAT) REGION

The Strategic Lateral Offset Procedure (SLOP) is now a standard operating procedure (SOP) throughout the North Atlantic (NAT) Region. This procedure mitigates collision risk and wake turbulence encounters. Pilots conducting oceanic flights within the NAT Region with automatic offset programming capability are recommended to fly lateral offsets up to 2 NM right of centerline.

The introduction of very accurate aircraft navigation systems, along with sophisticated flight management systems (FMS), has drastically reduced the number of risk-bearing lateral navigation (LNAV) errors reported in NAT airspace.

Paradoxically, the capability of aircraft to navigate to such a high level of accuracy has led to a situation in which aircraft on the same track, but at different levels, are increasingly likely to be in lateral overlap. This results in an increased risk of collision if an aircraft departs from its cleared level for any reason.

SLOP reduces risk by distributing aircraft laterally. It is applicable within the New York oceanic, Gander oceanic, Shanwick oceanic, Santa Maria oceanic, Nuuk, and Reykjavik flight information regions (FIRs), and within the Bodø oceanic FIR when flights are conducted more than 185 km (100 NM) seaward from the shoreline.

SLOP conforms to direction in the International Civil Aviation Organization's (ICAO) *Procedures for Air Navigation Services – Air Traffic Management* (Doc 4444) and is subject to the following guidelines:

- a. Aircraft without automatic offset programming capability must fly the route centerline.
- b. Operators capable of programming automatic offsets may fly the centerline or an offset up to a maximum of 2 NM right of centerline,
- c. Offsets to the left of centerline are not permitted.

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

- d. An aircraft overtaking another aircraft should offset within the confines of this procedure, if capable, so as to minimize the amount of wake turbulence for the aircraft being overtaken. The pilot should take into account wind, estimated wake vortex drift, and time to descend. (Nominal descent rates for wakes are 300–600 ft/min.)
- e. Pilots should use whatever means are available (e.g. traffic alert and collision avoidance system [TCAS], communications, visual acquisition) to determine the best flight path to fly. Pilots may contact other aircraft on frequency 123.45, as necessary, to coordinate the best wake turbulence offset option.
- f. Pilots may apply an offset outbound after the oceanic entry point and must return to center-line before the oceanic exit point. Position reports transmitted via voice should be based on the waypoints of the current ATC clearance and not the offset positions.
- g. There is no ATC clearance required for this procedure and it is not necessary that ATC be advised.

**11.22 CONTROLLER AND RADIO OPERATOR PROCEDURES (EXTRACTED
FROM ICAO DOC 10037 — GLOBAL OPERATIONAL DATA LINK
(GOLD) MANUAL, FIRST ED., 2017)**

11.22.1 Voice Communication Procedures

11.22.1.1 *Aeronautical Radio Operator – Response to Initial Contact*

1.22.1.1.1 Prior to or upon entering each NAT oceanic CTA, the flight crew should contact the appropriate aeronautical radio station.

11.22.1.1.2 The grounds system in all the aeronautical stations provides the aeronautical radio operators the flight's SELCAL code and FANS capabilities.

11.22.1.1.3 In response to the initial contact from the flight crew, the aeronautical radios operator should:

- a. assign the primary and secondary frequencies and complete the SELCAL check (see 11.24.1.1.3 for examples of the initial contact procedures to be used by the flight crew); and
- b. end the communication, if local procedures exist to deliver the communications instructions for the next CTA at a later stage, prior to the flight existing the current CTA; or
- c. issue the communications instructions and the frequency or frequencies to contact the next ATS unit or the aeronautical radio serving the next CTA.

11.22.1.2 *Aeronautical Radio Operator – Delayed CPDLC Messages*

If the flight crew advises "DELAYED CPDLC MESSAGE RECEIVED", they are explaining that a CPDLC message was received late. Flight crew procedures require voice contact to verify the message status. Aeronautical radio operators should include this notation when relaying the associated communication to ATC (see 4.2.1.9 and Appendix C. C.11 for flight crew procedures and 2.1.2.6 for further information regarding delayed CPDLC uplink messages – not published herein).

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

11.23 FLIGHT CREW PROCEDURES

11.23.1 Voice Communication Procedures

11.23.1.1 *Flight Crew – Contact with Aeronautical Radio Station*

11.23.1.1.1 The integrity of the ATC service remains wholly dependent on establishing and maintaining HF or VHF voice communications with each ATS unit along the route of flight. The procedures in this section are applicable only in NAT airspace and pertain only to ATS data link operations.

11.23.1.1.2 Prior to or upon entering each NAT oceanic CTA, the flight crew should contact the appropriate aeronautical radio station.

11.23.1.1.3 If the flight enters an oceanic CTA followed by another oceanic CTA, the flight crew should, on initial contact:

- a. not include a position report;
- b. after the radio operator responds, request a SELCAL check and state the next CTA;

NOTE: The radio operator will assign primary and secondary frequencies, perform the SELCAL check and designate the position and frequencies to contact the aeronautical radio station serving the next oceanic CTA.

- c. if the communications instructions are not issued at this stage, assume that the frequencies to use prior or upon entering the next CTA will be delivered at a later time by CPDLC or voice.

EXAMPLE: (Initial contact from an eastbound flight entering GANDER oceanic)

GANDER RADIO, AIRLINE 123, SELCAL CHECK, SHANWICK NEXT

AIRLINE 123, GANDER RADIO, HF PRIMARY 5616 SECONDARY 2899, AT 30 WEST CONTACT SHANWICK RADIO HF PRIMARY 8891 SECONDARY 4675 (SELCAL TRANSMITTED)

GANDER RADIO, AIRLINE 123, SELCAL OKAY, HF PRIMARY 5616 SECONDARY 2899. AT 30 WEST CONTACT SHANWICK RADIO, HF PRIMARY 8891 SECONDARY 4675.

11.23.1.1.4 If the flight will exit an oceanic CTA into continental airspace or surveillance airspace, on initial contact with the oceanic CTA, the flight crew should:

- a. not include a position report;
- b. after the radio operator responds, request a SELCAL check.

EXAMPLE: (Initial contact from an eastbound flight about to enter SHANWICK oceanic)

SHANWICK RADIO, AIRLINE 123, SELCAL CHECK

AIRLINE 123, HF PRIMARY 2899 SECONDARY 5616 (SELCAL TRANSMITTED)

SHANWICK RADIO, AIRLINE 123, SELCAL OKAY, HF PRIMARY 2899 SECONDARY 5616.

11.23.1.1.5 Depending on which. data link services are offered in the oceanic CTA and the operational status of those services, the aeronautical radio operator will provide appropriate infor-

CA 11
NORTH ATLANTIC (NAT) OPERATIONS

mation and instructions to the flight crew (see 11.23.1.1 for information regarding associated aeronautical radio operator procedures).

11.23.1.1.6 If a data link connection cannot be established, maintain normal voice communication procedures. In the event of data link connection failure in a NAT CTA after a successful logon, revert to voice and notify the appropriate radio station and AOC in accordance with established problem reporting procedures.

11.23.1.1.7 For ADS-C flights, the flight crew should not submit position reports via voice to reduce frequency congestion, unless requested by the aeronautical radio operator.

11.23.1.1.8 ADS-C flights are exempt from all routine voice meteorological reporting; however, the flight crew should use voice to report unusual meteorological conditions such as severe turbulence to the aeronautical radio station.

11.23.1.1.9 The flight crew should use CPDLC for any inquiries regarding the status of ADS-C connections. Should the ATS unit fail to receive an expected position report, the controller will follow the guidelines in 3.5.1.7 (not published herein) for late or missing ADS-C reports.

11.23.1.1.10 When leaving CPDLC/ADS-C or ADS-C-only airspace, the flight crew should comply with all communication requirements applicable to the airspace being entered.

11.23.1.1.11 If the flight crew does not receive its domestic frequency assignment by 10 minutes prior to the flight's entry into the next oceanic CTA, the flight crew should contact the aeronautical radio station and request the frequency, stating the current CTA exit fix or coordinates.

CA 12
ATC SPECIAL PROCEDURES

SECTION 12

12.1 ADHERENCE TO MACH NUMBER

- a. Within Canadian Domestic airspace, aircraft shall adhere to the Mach number assigned by ATC, to within 0.01 Mach, unless approval is obtained from ATC to make a change or until the pilot receives the initial descent clearance approaching destination. If it is essential to make an immediate temporary change in the Mach number (e.g., because of turbulence), ATC shall be notified as soon as possible that such a change has been made.
- b. If it is not possible, because of aircraft performance, to maintain the last assigned Mach number during enroute climbs and descents, pilots shall advise ATC at the time of the climb/descent request.

12.2 PARALLEL OFFSET PROCEDURES

- a. ATC may request that an aircraft fly a parallel offset from an assigned route. This maneuver and subsequent navigation is the responsibility of the pilot. When requested to offset or regain the assigned route, the pilot should change heading by 30 to 45° and report when the offset or assigned route is attained.
- b. In a radar environment, ATC will provide radar monitoring and the required separation.
- c. In a non-radar environment, ATC will apply parallel offsets to RNP-C-certified aircraft operating within high level RNP-C airspace in order to accomplish an altitude change with respect to same direction aircraft.
- d. The following phraseology is normally used for parallel offset procedures:

PROCEED OFFSET (number) MILES (right/left) OF CENTER LINE (track/route) AT (significant point/time) UNTIL (significant point/time)

12.3 STRUCTURED AIRSPACE

During specific periods, certain portions of domestic high level airspace may be structured for one-way traffic in which cruising flight levels inappropriate to the direction of the aircraft track may be assigned by ATC. Aircraft operating in a direction contrary to the traffic flow will be assigned those cruising flight levels appropriate to the direction of track except in specific instances, such as turbulence. When the airspace is not structured for one-way traffic, appropriate cruising flight levels will be used. ATC will transition aircraft to the appropriate cruising flight level for the direction of track before aircraft exit the defined areas or before termination of the indicated times.

12.4 CANADIAN DOMESTIC ROUTES

12.4.1 General

Within North American airspace, various route and track systems exist in order to provide effective management of airspace and traffic. Under specified conditions, random routes may be included in a flight plan or requested.

CA 12
ATC SPECIAL PROCEDURES

12.4.2 North American Route Program (NRP)

12.4.2.1 Introduction

The North American Route Program (NRP) is a joint FAA and NAV CANADA program that allows air operators to select operationally advantageous routings. The objective of the NRP is to harmonize and adopt common procedures, to the extent possible, applicable to random route flight operations at and above FL290 within the conterminous U.S. and Canada.

The NRP will be implemented through various phases with the end goal of allowing all international and domestic flight operations to participate in the NRP throughout the conterminous U.S. and Canada.

12.4.2.2 Eligibility

Flights may participate in the NRP under specific guidelines and filing requirements:

- a. provided the flight originates and terminates within conterminous U.S. and Canada; or
- b. for North Atlantic international flights, provided that they are operating within the North American Route (NAR) System.

12.4.2.3 Procedures

NRP common procedures and specific NAV CANADA requirements are contained in the Enroute section.

12.4.3 Mandatory Instrument Flight Rules (IFR) Routes

Air traffic controllers and ATS automated systems rely on certain set routes in order to plan systematic air traffic flows, a process that is critical for reducing delays. Mandatory IFR routes provide guidance in planning routes, minimize route changes, and allow for efficient departure, enroute, and arrival ATS while also reducing communication and the potential for readback and FMS input errors.

Procedures for and descriptions of mandatory routes are published in the ENROUTE — Canada — Low and High Altitude Mandatory Routes.

12.4.4 Fixed RNAV Routes

Published fixed RNAV routes can be flight planned for use by aircraft with RNAV capability, subject to any limitations or requirements noted on the enroute charts, in applicable advisory circulars, or by NOTAM.

- a. Q-routes are high-level fixed RNAV routes depicted on Enroute High Altitude charts using black dashed lines and require an RNAV system with performance capabilities currently only met by GNSS or distance measuring equipment/inertial reference unit (DME/DME/IRU) systems. DME/DME/IRU navigation may be limited in some parts of Canada owing to navigational facility coverage. In such cases, the routes will be annotated as “GNSS only” on the chart.
- b. T-routes are low-level controlled fixed RNAV routes depicted on Enroute Low Altitude charts using black dashed lines and require GNSS RNAV systems for use. The airspace associated

CA 12

ATC SPECIAL PROCEDURES

with T-routes extends upward from 2200 ft AGL, 10 NM either side of the centerline, and does not splay. The MOCA provides obstacle protection for only 6 NM either side of the track centerline and does not splay.

- c. L-routes are low-level uncontrolled fixed RNAV routes depicted on Enroute Low Altitude charts using green dashed lines and require GNSS RNAV systems for use. The MOCA provides obstacle protection for only 6 NM either side of the track centerline and does not splay. Magnetic reference bearing (MRB) is the published bearing between two waypoints on a fixed RNAV route and will be published within the SDA. The MRB is calculated by applying magnetic variation at the waypoint to the calculated true course between two waypoints. Pilots should use this bearing as a reference only, because RNAV systems will fly the true course between the waypoints.

True reference bearings (TRB) will be published along fixed RNAV routes located in the NDA and shall be notated with the suffix "T."

12.4.5 Northern Control Area Random Routes

Within the Northern Control Area (NCA) flights operating on random routes shall make positions reports as follows:

- a. flights operating on predominately north or south tracks (315°T clockwise through 045°T or the reciprocals) shall report over reporting line points formed by the intersection of parallels of latitude spaced at 5° intervals expressed in latitude by whole degrees and meridians of longitude expressed in either whole degrees or whole and half degrees;
- b. south of 75°N latitude, flights operating on predominately east or west tracks (046°T clockwise through 134°T or the reciprocals) shall report over reporting line points formed by the intersection of either whole degrees or whole and half degrees of latitude coincident with each 10° of longitude. For flights operating north of 75°N latitude, where 20° of longitude is traversed in less than 60 minutes, reporting line points are to be defined by parallels of latitude expressed in degrees and minutes coincident with meridians of longitude at 20° intervals;
- c. as requested by ATS.

12.4.6 Arctic Control Area Random Routes

Within the Arctic Control Area (ACA), flights operating on random routes shall make positions reports as follows:

- a. at the reporting lines coincident with 141 degrees W, 115 degrees W and 60 degrees W meridians. If the route of flight is north of 87 degrees N latitude, the 115 degrees W report is not required;
- b. westbound flights which do not cross the 60 degrees W meridian on entry or prior to entry into the ACA shall report at the point of entry into the ACA;
- c. westbound flights which do not cross the 141 degrees W meridian prior to exiting the ACA shall report at the point of exit from the ACA;

CA 12
ATC SPECIAL PROCEDURES

- d. eastbound flights which do not cross the 141 degrees W meridian on entry into the ACA shall report at the point of entry;
- e. eastbound flights which do not cross the 60 degrees W meridian on or after exiting the ACA shall report the point of exit;
- f. northbound or southbound flights which do not cross significant reporting lines shall report at the entry and exit points of the ACA; and
- g. as requested by ATS.

12.4.7 Polar Routes

12.4.7.1 General

With the advent of aircraft capable of long-range flight, circumventing the globe via the North Pole has become routine. Polar routes are flight paths to or from the Americas and Eurasia via Russian polar airspace. Polar flights must file designated polar fixes on the Anchorage/Russian border but are otherwise random in Canadian airspace.

12.4.7.2 Flight Planning and Position Reporting

Polar routes can be flight planned by aircraft with CMNPS certification. Flight plan routing should be filed with a fix every 5° of latitude. Random points should be expressed in whole degrees of latitude and either whole degrees or whole and half degrees of longitude.

12.4.7.3 Altitude Assignment

Current cruising altitude for direction of flight requirements are based on east-west traffic flows. A shift in flight track (from east to west or vice versa) requires the assignment of a new flight level. Flights on north-south routes may shift track, from easterly to westerly or vice versa, depending on route segment. This shifting makes altitude assignment based on current regulations less than optimal.

In order to accommodate polar route flights, aircraft operating on polar routes within the Edmonton, Winnipeg and Montréal FIRs may be assigned altitudes inappropriate to the direction of flight. Altitude assignment is based on traffic management requirements for the movement of aircraft in a safe, orderly and expeditious manner.

12.5 NORTHERN AMERICAN ROUTE (NAR) SYSTEM

- a. The NAR System provides an interface between NAT oceanic and domestic airspaces. Operating conditions and description of the NAR are contained in STRUCTURED AIRSPACE above and the ENROUTE section.
- b. For a detailed description of the NAR System, refer to ENROUTE NORTH AMERICAN ROUTES FOR NORTH ATLANTIC TRAFFIC that outlines the requirements to flight plan and operate using the NAR system.

CA 12
ATC SPECIAL PROCEDURES

12.6 EMERGENCY SECURITY CONTROL OF AIR TRAFFIC (ESCAT) PLAN

In Canadian airspace, the ESCAT Plan provides security control of civil and military air traffic to ensure effective use of airspace when an air defence emergency or any situation involving aerial activities that threatens national security or vital Canadian interests is declared by the appropriate authority. The Plan outline highlights responsibilities, procedures, and instructions for the security control of civil and military air traffic with respect to diversion, landing, grounding and dispersal. The ESCAT Plan was developed in co-ordination with DND, Transport Canada, and NAV CANADA.

The Commander, Canadian North American Aerospace Defence Command (NORAD) Region (CANR), is responsible for testing and implementing the ESCAT Plan. When the ESCAT Plan is implemented or tested, the appropriate NAV CANADA ACCs (through ATS units), under the direction of the National Defence Command Centre (NDCC), will take actions to broadcast instructions through civil and military ATS units as necessary.

Testing

To ensure the effectiveness of communications during the implementation of the ESCAT Plan, periodic tests may be conducted without any prior notice.

The test message will be broadcast as follows:

“ATTENTION—THIS IS AN ESCAT TEST. I SAY AGAIN, THIS IS AN ESCAT TEST.”

As these tests are considered essential to national security, co-operation of all pilots and agencies is necessary.

Implementation

In an emergency situation, the appropriate NAV CANADA ACC (through their respective ATS units), under directions of the Commander, CANR, will broadcast the following message:

“ATTENTION ALL AIRCRAFT—AIR DEFENCE EMERGENCY—ALL AIRCRAFT WILL COMPLY WITH THE PROCEDURES FOR THE EMERGENCY SECURITY CONTROL OF AIR TRAFFIC. VFR TRAFFIC ON THIS FREQUENCY MUST LAND AT THE NEAREST SUITABLE AIRFIELD AND FILE AN IFR OR DVFR FLIGHT PLAN.”

In accordance with CAR 602.146, the pilot-in-command of an aircraft who is notified by an ATC unit of the implementation of the ESCAT Plan shall:

- a. before take-off, obtain approval for the flight from the appropriate ATC unit or FSS;
- b. comply with any instruction to land or to change course or altitude that is received from the appropriate ATC unit or FSS; and
- c. provide the appropriate ATC unit or FSS with position reports
 1. when operating within controlled airspace, as required pursuant to CAR 602.125; and
 2. when operating outside controlled airspace, at least every 30 min.

ESCAT Phases

ESCAT may be implemented in phases to facilitate a smooth transition from normal peacetime air traffic identification and control procedures to the more restrictive identification and control proce-

CA 12
ATC SPECIAL PROCEDURES

dures that accompany the full implementation of the ESCAT. When ESCAT has been implemented, the movement of civil and military aircraft is governed by the implementation of an ESCAT Air Traffic Priority List (EATPL) and/or a Security Control Authorization (SCA).

There are two phases in the implementation process.

- *Phase One:* Requires all aircraft in designated areas to file IFR/DVFR flight plans in accordance with CARs 602.76(1) and (2), CAR 602.145, this Plan and the established procedures detailed in the CFS (GPH 205).
- *Phase Two:* The Commander, CANR, restricts aircraft movement within designated areas through the implementation of the EATPL and SCA process.

NOTE: EATPL and SCA approval request procedures will be promulgated by NOTAM.

ESCAT Zones

For the purpose of implementing the ESCAT, Canadian airspace has been divided into seven zones. During implementation, one or more zones, or portions of zones, may be activated (see Figure 12.1).

CA 12
ATC SPECIAL PROCEDURES

Figure 12.1 — Map of ESCAT Zones

NOTE: Coordinates for the ESCAT Zones are published in the DAH (TP 1820).

Termination

The appropriate NAV CANADA ACC (through their respective ATS units) will broadcast the following message:

"ATTENTION ALL AIRCRAFT—EMERGENCY SECURITY CONTROL OF AIR TRAFFIC HAS BEEN TERMINATED. ROUTINE AIRSPACE PROCEDURES ARE NOW IN EFFECT."

For more information about the ESCAT Plan, please contact:

Transport Canada Aviation Operations (AVOPS)

ATC SPECIAL PROCEDURES

613-992-6853

or

NAV CANADA National Operations Centre

Tel: 1-866-651-9053

12.7 ABNORMALLY HIGH ALTIMETER SETTINGS

Cold dry air masses can produce barometric pressures in excess of 31.00 in. of mercury. Because barometric readings of 31.00 in. of mercury or higher rarely occur, most standard altimeters do not permit setting of barometric pressures above that level and are not calibrated to indicate accurate aircraft altitude above 31.00 in. of mercury. As a result, most aircraft altimeters cannot be set to provide accurate altitude readouts to the pilot in these situations.

When aircraft operate in areas where the altimeter setting is in excess of 31.00 in. of mercury and the aircraft altimeter cannot be set above 31.00 in. of mercury, the true altitude of the aircraft will be HIGHER than the indicated altitude.

12.8 TRAFFIC ALERT AND COLLISION AVOIDANCE SYSTEMS AND AIRBORNE COLLISION AVOIDANCE SYSTEMS

12.8.1 General

The International Civil Aviation Organization (ICAO) uses the term airborne collision avoidance system (ACAS). The term traffic alert and collision avoidance system (TCAS) refers to the system developed in the United States by the Federal Aviation Administration (FAA). These terms are generally interchangeable. Care needs to be taken when comparing ICAO definitions of ACAS II with the North American definition of TCAS II. Specifically, the ICAO definition of a fully compliant ACAS II (see ICAO Annex 10, Volume 4, Chapter 4) is equivalent to TCAS II software version 7.1. Additional guidance and information on ACAS may be found in Transport Canada (TC) Advisory Circular (AC) 700-004.

NOTE: For the purposes of the Transport Canada Aeronautical Information Manual (TC AIM), the term TCAS will be used and, where necessary, a specific software version will be identified for clarity.

TCAS equipment alerts flight crews when the path of the aircraft is predicted to potentially collide with that of another aircraft. TCAS-equipped aircraft interrogates other aircraft in order to determine their position. TCAS is designed to operate independently of ATC and, depending on the type of TCAS, will display proximate traffic and provide TAs and RAs.

- a. TAs provide information on proximate traffic and indicate the relative positions of intruding aircraft. TAs are intended to assist the flight crew in visual acquisition of conflicting traffic and to prepare the pilots for the possibility of an RA.
- b. RAs are divided into two categories: preventative advisories, which instruct the pilot to maintain or avoid certain vertical speeds, and corrective advisories, which instruct the pilot to deviate from the current flight path (e.g., "CLIMB" when the aircraft is in level flight).

CA 12
ATC SPECIAL PROCEDURES

There are two types of TCAS:

- a. TCAS I is a system including a computer and pilot display(s), which provides a warning of proximate traffic (TA) to assist the pilot in the visual acquisition of intruder aircraft and in the avoidance of potential collisions (it does not provide RAs).
- b. TCAS II is a system including a computer, pilot display(s), and a Mode S transponder, which provides both TAs and vertical plane RAs. RAs include recommended escape maneuvers, only in the vertical dimension to either increase or maintain existing vertical separation between aircraft.

NOTE: There is currently no TCAS equipment capable of providing RAs in the lateral direction.

The following paragraphs and table describe the TCAS levels of protection versus aircraft equipment.

- a. Intruder aircraft without transponders are invisible to TCAS-equipped aircraft and thus TAs or RAs are not provided.
- b. Intruder aircraft equipped with only a Mode A transponder are not tracked or detected by TCAS II, because TCAS II does not use Mode A interrogations. Mode A transponder aircraft are invisible to TCAS-equipped aircraft.
- c. Intruder aircraft equipped with a Mode C transponder without altitude input will be tracked as a non-altitude replying target. Neither a data tag nor a trend arrow will be shown with the traffic symbol. These aircraft are deemed to be at the same altitude as own aircraft.
- d. In an encounter between two TCAS II-equipped aircraft, their computers will communicate using the Mode S transponder data link, which has the capability to provide complementary RAs (e.g., one climbing and one descending).

Table 12.1 — TCAS Levels of Protection

		Own Aircraft Equipment	
		TCAS I	TCAS II
Intruder Aircraft Equipment	Non-XPDR-equipped or Mode A XPDR ONLY	Not tracked & not displayed	Not tracked & not displayed
	Mode C or Mode S XPDR	TA	TA and vertical RA
	TCAS I	TA	TA and vertical RA
	TCAS II	TA	TA and coordinated vertical RA

12.8.2 Transport Canada TCAS/ACAS Regulations

The Technical Standard Order (TSO) for TCAS I is TSO-C118 or CAN-TSO-C118.

CA 12
ATC SPECIAL PROCEDURES

The TSO for TCAS II/ACAS II is TSO-C119 or CAN-TSO-C119. The original release of TSO-C119 was associated with software version 6.0. Since then the following updates to TSO-C119 have been released:

- a. TSO-C119a (*associated with software version 6.04a*)— Version 6.04a was released to address nuisance alerts which were occurring at low altitudes and during low-level maneuvers, and to address a problem with the altitude crossing logic.

NOTE: This version is the minimum requirement for operations in Canada when outside of RVSM airspace;

- b. TSO-C119b (*associated with software version 7.0*)— Version 7.0 was released to address numerous enhancements to the collision avoidance algorithms, aural annunciation and RA displays, and changes to reduce repetitive nuisance TAs on RVSM routes in slow closure situations.

NOTE: Software version 7.0 is the minimum required for all CAR 702, 703, 704 and 705 aeroplanes when operating inside of RVSM airspace;

- c. TSO-C119c (*associated with software version 7.1*)— Version 7.1 was released to address reversal logic issues and address flight crew misinterpretation of “ADJUST VERTICAL SPEED, ADJUST” aural annunciation. In ICAO terminology this is also referred to as ACAS II.

NOTE 1: In Amendment 85 to ICAO Annex 10, Volume IV, Chapter 4, published in October 2010, ICAO has mandated that all new ACAS installations after 1 January 2014 be compliant with version 7.1 and all ACAS units shall be compliant with version 7.1 after January 2017. Transport Canada has not initiated any rulemaking based on these ICAO requirements.

NOTE 2: Be advised that if you operate in ICAO member countries after the above-mentioned dates you will have to equip with software version 7.1.

Within some member states such as the European Community and within European Civil Aviation Conference (ECAC) airspace, equipage with TCAS II software version 7.1 will be required earlier than the ICAO mandated dates.

The TSO for Mode S transponders is TSO-C112 or CAN-TSO-C112.

The following table and associated notes summarizes the TCAS/ACAS requirements for CAR Part VII air operators.

CA 12
ATC SPECIAL PROCEDURES

Table 12.2 — TCAS/ACS Requirements for CAR Part VII Air Operators

Canadian Aviation Regulation	TCAS I Equivalent to CAN-TSO-C118	TCAS II CAN-TSO-C119a (SW 6.04a) outside of RVSM airspace or CAN-TSO-C119b (SW 7.0) inside of RVSM airspace and Mode S transponder CAN-TSO- C112
702.46	Not required	Required for turbine-powered aeroplanes of maximum certified takeoff weight (MCTOW) exceeding 15,000kg (33,069 lb). (Notes 1 and 2)
703.70	Minimum required for aeroplanes of MCTOW exceeding 5700kg (12,566 lb) outside of RVSM airspace. (Note 1)	Not required but acceptable outside of RVSM airspace Required when operating in RVSM airspace. (Note 1).
704.70	Minimum required for aeroplanes of MCTOW exceeding 5700kg (12,500 lb) outside of RVSM airspace. (Note 1)	Required for turbine-powered aeroplanes of MCTOW exceeding 15,000kg (33,069 lb). (Note 1)
705.83	Minimum required for non-turbine-powered aeroplanes outside of RVSM airspace. (Note 1)	Required for turbine-powered aeroplanes. (Note 1)

NOTE 1: TCAS II, CAN-TSO C119b (software version 7.0) or more recent and Mode S transponder CAN-TSO-C112 or more recent, are required for operations in RVSM airspace.

NOTE 2: Not required when engaged in or configured for firefighting, aerial spray services, or aerial survey and operates only in low-level airspace.

It is strongly recommended that foreign operators comply with TCAS equipage requirements as outlined above when operating within Canadian airspace.

There are currently no CARs requiring private operators (CAR 604) to equip with TCAS equipment. However, private operators are advised that ICAO Annex 6, Part II, Chapter 3.6.10.2 requires that: "All turbine-engined aeroplanes of a maximum certificated take-off mass in excess of 15,000kg or authorized to carry more than 30 passengers, for which the individual airworthiness certificate is first issued after 1 January 2007, shall be equipped with an airborne collision avoidance system (ACAS II)". This means that affected private operators, flying into ICAO member countries must be equipped with ACAS II.

CA 12

ATC SPECIAL PROCEDURES

12.8.3 Use of TCAS outside of Canada

Numerous countries world wide have operational regulations which require certain aircraft to be equipped with TCAS. If you are planning on operating your aircraft in a foreign country consult that country's regulations to determine TCAS equipage requirements.

Canadian air operators must meet the following TCAS requirements to operate in U.S. airspace (see FAA FAR 129.18):

- a. TCAS I: Turbine-powered airplane with a passenger-seat configuration, excluding any pilot seat, of 10-30 seats.
- b. TCAS II: Turbine-powered airplane of more than 33,000 lb maximum certificated takeoff weight (MCTOW).

Canadian air operators planning operations into U.S. airspace are advised to review FAA Advisory Circular 120-55C — *Air Carrier Operational Approval and Use of TCAS II* (as amended).

For Canadian air operators planning operations in Europe, details of European requirements are available at: www.eurocontrol.int/acas/.

12.8.4 Operational Approval

For Canadian air operators, TCAS operational approval is accomplished through Transport Canada approval of: pertinent training; checking and currency programs; checklists; SOP operations or training manuals; maintenance programs; minimum equipment lists or other pertinent documents.

When planning to equip with TCAS, Canadian air operators should consult their Transport Canada principle operations inspector (POI) early in their program to permit a timely response. Canadian air operators may address the training, checking and currency individually or as part of an integrated program. For example, TCAS/ACAS qualification may be keyed to qualification of specific aircraft (e.g., during A320 transition), may be addressed in conjunction with general flight crew qualification (e.g., during initial new hire indoctrination), or may be completed as dedicated TCAS/ACAS training and checking (e.g., by completion of a standardized TCAS/ACAS curriculum in conjunction with a recurrent IFT/PPC event).

FAA Advisory Circular 120-55C — *Air Carrier Operational Approval and Use of TCAS II* (as amended) provides information with respect to training, checking and currency in the use of TCAS. The material therein can be used by operators to assist in defining their implementation of TCAS.

EUROCONTROL has produced and published TCAS training material and information available at: www.eurocontrol.int/acas/.

12.8.5 Aircraft Certification Approval

An acceptable means of demonstrating compliance with the appropriate requirements of the *Airworthiness Manual*, Chapter 525, to obtain airworthiness approval, is to follow the method specified in FAA Advisory Circular AC20-131A — *Airworthiness Approval of Traffic Alert and Collision Avoidance Systems (TCAS II) and Mode S Transponders* (as amended) for installation of TSO-C119a TCAS/ACAS. FAA Advisory Circular AC20-151B — *Airworthiness Approval of Traffic Alert*

CA 12

ATC SPECIAL PROCEDURES

and Collision Avoidance Systems (TCAS II), Versions 7.0 & 7.1 and Associated Mode S Transponders, should be followed for installations using TSO-C119b or TSO-C119c equipment.

12.8.6 Operational Considerations

- a. Where required by regulations to be equipped with TCAS, flight crews must operate with their TCAS equipment on at all times, in so far as is consistent with the AFM (Aircraft Flight Manual) and SOPs. This is true even when operating away from major, high traffic density airports. Although TCAS will never be a complete substitute for a good lookout, good situational awareness and proper radio procedures, it has been proven to be a valuable tool in providing information on potential collision hazards. Hence flight crews should not deprive themselves of this important asset, especially in areas of mixed IFR and VFR traffic.
- b. For a TCAS-equipped aircraft to provide a flight crew with collision avoidance information the TCAS unit and the transponder must be turned on, the transponder cannot be selected to the STANDBY mode (that is, powered but not transmitting data). If the transponder is not turned on and responding to interrogations, the aircraft's TCAS cannot display information about potentially conflicting aircraft nearby nor can it provide instructions to the crew to resolve impending collision threats. Failures of the TCAS computer unit itself can also occur; however, these failures only affect the TCAS-equipped aircraft's ability to detect nearby aircraft. The aircraft containing the inoperative TCAS unit remains visible to other aircraft as long as its transponder remains operative. The consequences of a TCAS unit failure are magnified, however, when the transponder is inoperative because, not only is TCAS information lost on the affected aircraft, but that aircraft will not be visible to other airborne collision avoidance systems. Regardless of whether the transponder has failed or the TCAS has become inoperative, a flight crew's ability to mitigate the risk of collision is significantly degraded if the collision avoidance system becomes inoperative and the failure is not quickly and reliably brought to the crew's attention. Air operators are encouraged to inform their pilots who use transponders or transponder/TCAS units about the potential lack of a conspicuous warning to indicate the loss of collision protection resulting from a compromise in functionality of either the transponder or TCAS unit. Air operators should require all pilots who use transponders or transponder/TCAS units to become familiar with the annunciations currently used to indicate failure or lack of active functionality of these components.
- c. Flight crews are reminded to follow the RAs promptly and accurately, even though the RAs may change in strength and/or reverse. RA commands do not require large load factors when being followed. Any delay in responding to an RA could swiftly erode the ability to maintain or achieve adequate separation without resorting to strengthening RAs. For TCAS to provide safe vertical separation, initial vertical speed response is required within 5 seconds of the RA. Deviation from commands or second-guessing the commands should not occur. An RA prevails over any ATC instruction or clearance.
- d. Flight crews may have to inhibit the RA function under certain circumstances per the AFM (e.g., during an engine failure).
- e. The TCAS system may inhibit RAs during certain flight phases, such as at low altitudes. Flight crews need to be aware of when TCAS will not provide a full range of RA commands.

CA 12

ATC SPECIAL PROCEDURES

- f. Flight crews should not attempt to maneuver solely on the basis of TA information. The TA should trigger a visual search for traffic, supplemented with a request for ATC assistance to help in determining whether a flight path change is required. In the case of a TCAS II TA, the flight crew should prepare for a possible RA, following the TA.
- g. TAs and RAs should be treated as genuine unless the intruder has been positively identified and assessed as constituting neither a threat nor a hazard.
- h. Flight crews should be aware that in accordance with the *Canadian Transportation Accident Investigation and Safety Board Act*, an incident where a risk of collision or a loss of separation occurs is considered a reportable aviation incident. Responding to an RA is considered a reportable aviation incident. For more information on this topic, visit the following links:
 - 1. [AC 700-004: Airborne Collision Avoidance System Advisory Material](#); and
 - 2. www.tc.gc.ca/en/services/aviation/operating-airports-aerodromes/report-incident-airport-safety.html.
- i. If a TCAS RA maneuver is contrary to other critical cockpit warnings, then those other critical warnings are respected as defined by TCAS certification and training (that is, responses to stall warning, wind shear and terrain awareness and warning systems (TAWS) take precedence over a TCAS RA, especially when the aircraft is less than 2500 ft AGL.)
- j. Due to interference limiting algorithms, ACAS II may not display all proximate transponder-equipped aircraft in areas of high density traffic. Flight crew vigilance must be maintained and flight crews should not become complacent in their efforts to search the sky for other aircraft.

12.8.7 Pilot Action When Deviating from Clearances: Regulations and Information

Safety studies have confirmed that the significant safety benefit afforded by TCAS could be seriously degraded by a deficient response to RAs. It has also been shown that the safety benefit of TCAS is eroded when pilots do not follow the flight path guidance provided during an RA.

In view of this safety hazard and to optimize the safety benefits of TCAS, the following regulatory provisions have been established:

CAR 602.31(3) of the CARs states that:

“The pilot-in-command of an aircraft may deviate from an air traffic control clearance or an air traffic control instruction to the extent necessary to carry out a collision avoidance maneuver, where the maneuver is carried out

- a. in accordance with a resolution advisory generated by an ACAS; or
- b. in response to an alert from a TAWS or a Ground Proximity Warning System (GPWS).”

CAR 602.31(4) states that:

“The pilot-in-command of an aircraft shall

- a. as soon as possible after initiating the collision avoidance manoeuvre referred to in subsection (3), inform the appropriate air traffic control unit of the deviation; and

CA 12

ATC SPECIAL PROCEDURES

- b. immediately after completing the collision avoidance manoeuvre referred to in subsection (3), comply with the last air traffic control clearance received and accepted by, or the last air traffic control instruction received and acknowledged by, the pilot-in-command.”

NOTE: By following the RA guidance precisely, the magnitude of the altitude deviation can be minimized. Pilots must ensure that the maneuver necessary to comply with the RA (climb or descent) is not maintained after the RA has terminated.

There is information available which highlights the importance of following RAs. EUROCONTROL has issued numerous ACAS II bulletins (www.eurocontrol.int/acas/). ACAS II Bulletin Number 2 *Follow the RA*, dated July 2002, describes several RA events and the consequences of the flight crew actions taken. The bulletin is informative in describing the advantages of TCAS/ACAS for collision avoidance, when followed correctly. The bulletin also describes the limitations associated with the visual acquisition of traffic and those of ATC radar displays.

Transport Canada recommends that operators disseminate this information to pilots for awareness, and where appropriate, establish suitable pilot training programs to ensure that flight crews follow RAs promptly and accurately, even when presented with conflicting avoidance instructions from ATC.

12.8.8 Mode S Transponder Approval and Unique Codes

Along with performing all the functions of Mode A and C transponders, Mode S transponders also have a data link capability. Mode S transponders are an integral component of all TCAS II/ACAS II installations.

For aircraft that are not required to be equipped with TCAS/ACAS, there is no requirement to replace existing Mode A or C transponders with Mode S transponders until it becomes impossible to maintain presently installed Mode A and C transponders.

Airworthiness approval must be obtained by Canadian aircraft operators who install Mode S transponders. FAA Advisory Circular AC20-131A – *Airworthiness Approval of Traffic Alert and Collision Avoidance Systems (TCAS II) and Mode S Transponders* (as amended) should be used for guidance to obtain airworthiness approval. Canadian operators should contact their Regional Transport Canada office for approval details.

At the time of registration, each Canadian aircraft with a Mode S transponder will receive a unique 24-bit Mode S code assignment, which must be uploaded in the transponder, usually by the installer.

12.8.9 Pilot/Controller Actions

In order to use TCAS in the most effective and safest manner, the following pilot and controller actions are necessary:

- a. Pilots should not maneuver their aircraft in response to TAs only;
- b. In the event of an RA to alter the flight path, the alteration of the flight path should be limited to the minimum extent necessary to comply with the RA (aggressive maneuvering should not be required since TCAS RAs are predicted on $\frac{1}{4}$ G maneuver load factors);

CA 12

ATC SPECIAL PROCEDURES

- c. Pilots should notify, as soon as possible, the appropriate ATC unit of the deviation and when the deviation has ended.
- d. When a pilot reports a maneuver induced by an RA, the controller should not attempt to modify the aircraft flight path until the pilot reports returning to the terms of the existing ATC instruction or clearance. Instead, the controller should provide traffic information as appropriate.
- e. Pilots who deviate from an ATC instruction or clearance in response to an RA shall promptly return to the terms of that instruction or clearance when the conflict is resolved and advise ATC.

12.8.10 Pilot and Controller Phraseology

The current ICAO traffic alert and collision avoidance system (TCAS) pilot/controller phraseology is detailed below (see also ICAO Doc 4444 PANS Air Traffic Management, Chapter 12, Paragraph 12.3.1.2). It should be noted that, for the purpose of phonetic clarity, the term TCAS is used.

Table 12.3 — TCAS Pilot-Controller Phraseology

Circumstances	Pilot	Controller
After a flight starts to deviate from the ATC clearance or instructions to comply with a TCAS RA.	TCAS RA	ROGER
After the response to a TCAS RA is completed and a return to the ATC clearance or instruction is initiated.	CLEAR OF CONFLICT. RETURNING TO (assigned clearance)	ROGER (or alternate instructions)
After the response to a TCAS RA is completed and the assigned ATC clearance or instruction has been resumed.	CLEAR OF CONFLICT. (assigned altitude) RESUMED	ROGER (or alternate instructions)
After an ATC clearance or instruction contradictory to the TCAS RA is received, the flight crew will follow the RA and inform ATC directly.	UNABLE, TCAS RA;	ROGER

12.9 REDUCED VERTICAL SEPARATION MINIMUM (RVSM)

12.9.1 Definition

RVSM — The application of 1000 ft vertical separation at and above FL290 between aircraft approved to operate in reduced vertical separation minimum airspace.

Non-RVSM Aircraft — An aircraft that does not meet reduced vertical separation minimum (RVSM) requirements for certification and/or for operator approval.

CA 12
ATC SPECIAL PROCEDURES

RVSM Aircraft — An aircraft that meets reduced vertical separation minimum (RVSM) requirements for certification and for operator approval.

12.9.2 RVSM Airspace

- a. RVSM airspace is all airspace within CDA from FL290 to FL410 inclusive as defined in the DAH (TP 1820) and depicted in Figure 12.2.

CA 12
ATC SPECIAL PROCEDURES

Figure 12.2 — RVSM Airspace and RVSM Transition Airspace

CA 12
ATC SPECIAL PROCEDURES

12.9.3 ATC Procedures

a. Within RVSM airspace ATC:

1. will, within *non-radar* airspace, endeavour to establish 2000 ft separation or applicable lateral or longitudinal separation minimum if an aircraft reports greater-than-moderate turbulence, and/or mountain wave activity that is of sufficient magnitude to significantly affect altitude-keeping, and is within 5 min of another aircraft at 1000 ft separation;
2. will, within *radar* airspace, vector aircraft to establish radar separation or establish 2000 ft separation if an aircraft reports greater-than-moderate turbulence, or encountering mountain wave activity that is of sufficient magnitude to significantly affect altitude-keeping, if 1000 ft vertical separation exists between two aircraft, and targets appear likely to merge;
3. may structure portions of the airspace for specific periods of time for one-way traffic in which inappropriate flight levels to the direction of flight may be assigned; and
4. may, within non-radar airspace, temporarily suspend RVSM within selected areas and/or altitudes due to adverse weather conditions, e.g. pilot reports greater-than-moderate turbulence. When RVSM is suspended, the vertical separation minimum between all aircraft will be 2000 ft.

b. Pilots may be requested by ATC to confirm that they are approved for RVSM operations. Pilots/operators unable to provide such confirmations will be issued a clearance to operate outside RVSM airspace:

Phraseology: "Affirm RVSM" or "Negative RVSM (supplementary information, e.g. monitoring flight)." See phraseology depicted in Figure 12.3

12.9.4 In-Flight Procedures

a. Before entering RVSM airspace, the status of required equipment should be reviewed. The following equipment should be operating normally:

1. two independent altitude measurement systems;
2. one automatic altitude-control system; and
3. one altitude alert system

b. The pilot must notify ATC whenever the aircraft:

1. is no longer RVSM-compliant due to equipment failure;
2. experiences loss of redundancy of altimetry systems; or
3. encounters turbulence or mountain wave activity that affects the capability to maintain the cleared flight level.

c. In the event that any of the required equipment fails prior to entering RVSM airspace, a new clearance should be requested in order to avoid RVSM airspace.

CA 12
ATC SPECIAL PROCEDURES

- d. In level cruise, it is essential that the aircraft maintains the cleared flight level. Except in contingency situations, aircraft should not deviate from the cleared flight level without an ATC clearance. If the pilot is notified by ATC of an assigned altitude deviation (AAD) error 300 ft. or greater, the pilot should return to the cleared flight level as soon as possible.
- e. **TRANSITION BETWEEN FLs:** During cleared transition between flight levels, the aircraft should not overshoot or undershoot the assigned level by more than 150 ft.

12.9.5 Flight Planning Requirements

- a. Unless an aircraft can be accommodated in RVSM airspace as detailed in ATC paragraph 12.16.6, RVSM approval is required for aircraft to operate within RVSM airspace. The operator must determine that the aircraft has been approved by the appropriate State authority and will meet the RVSM requirements for the filed route of flight and any planned alternate routes. The letter "W" shall be inserted in Item 10 (Equipment) of the flight plan to indicate that the aircraft is RVSM-compliant and the operator is RVSM-approved. The "W" designator is not to be used unless both conditions are met. If the aircraft registration is not used in Item 7, the registration is to be entered in Item 18 (ATC Flight Planning para 3.16.8 "REG/").
- b. ATC will use the equipment block information to either issue or deny clearance into RVSM airspace and to apply either 1000 ft or 2000 ft vertical separation minimum.
- c. Non-RVSM aircraft requesting permission to operate in RVSM airspace shall include "STS/ NONRVSM" in item 18 of the flight plan to indicate the reason for special handling by ATS.

12.9.6 Operation of Non-RVSM Aircraft in RVSM Airspace

- a. **FLIGHT PRIORITY:** RVSM aircraft will be given priority for flight level allocation over non-RVSM aircraft. Non-RVSM aircraft may be accommodated on a traffic- and workload-permitting basis.
- b. **VERTICAL SEPARATION:** The vertical separation minimum between non-RVSM aircraft operating in RVSM airspace and all other aircraft is 2000 ft.
- c. **CONTINUOUS CLIMB OR DESCENT THROUGH RVSM AIRSPACE:** Non-RVSM aircraft may be cleared to climb to and operate above FL410 or descend to and operate below FL290, provided the aircraft is capable of:
 - 1. a continuous climb or descent and does not need to level off at an intermediate altitude for any operational considerations; and
 - 2. climb or descent at the normal rate for the aircraft.
- d. **STATE AIRCRAFT:**

For the purposes of RVSM operations, State aircraft are those aircraft used in military, customs and police services.

State aircraft are exempt from the requirement to be RVSM approved to operate in RVSM airspace;
- e. **NON-RVSM AIRCRAFT IN RVSM AIRSPACE:**

CA 12
ATC SPECIAL PROCEDURES

Non-RVSM aircraft may flight plan within RVSM airspace, provided the aircraft:

1. is being delivered to the State of Registry or Operator;
2. was formerly RVSM-approved but has experienced an equipment failure and is being flown to a maintenance facility for repair in order to meet RVSM requirements and/or obtain approval;
3. is being utilized for mercy or humanitarian purposes;
4. is a photographic survey flight (CDA only). This approval is not applicable for that portion of flight transiting to and from the area(s) of surveying or mapping operations;
5. is conducting flight checks of a NAVAID. This approval is not applicable for that portion of flight transiting to and from the area(s) of flight check operations; or
6. is conducting a monitoring, certification or developmental flight.

f. PHRASEOLOGY:

Pilots of non-RVSM flights should include the phraseology "Negative RVSM" in all initial calls on ATC frequencies, requests for flight level changes, read backs of flight level clearances within RVSM airspace and read back of climb or descent clearances through RVSM airspace. See Figure 12.2.

12.9.7 Delivery Flights for Aircraft that are RVSM Compliant on Delivery

- a. An aircraft that is RVSM-compliant on delivery may operate in Canadian Domestic RVSM airspace provided that the crew is trained on RVSM policies and procedures applicable in the airspace and the responsible State issues the operator a letter of authorization approving the operation.
- b. State notification to the NAARMO (see para 12.8.9) should be in the form of a letter, e-mail or facsimile documenting the one-time flight indicating:
 1. planned date of the flight;
 2. flight identification;
 3. registration number; and
 4. aircraft type/series.

12.9.8 Airworthiness/Operational Approval And Monitoring

- a. Operators must obtain airworthiness and operational approval from the State of Registry or State of the Operator, as appropriate, to conduct RVSM operations. For the purposes of RVSM, the following terminology has been adopted:
 1. **RVSM Airworthiness Approval:** The approval that is issued by the appropriate State authority to indicate that an aircraft has been modified in accordance with the relevant approval documentation, e.g., service bulletin, supplemental type certificate, and is therefore eligible for monitoring. The date of issue of such an approval should coincide with the date when the modification was certified by the operator as being complete.

CA 12
ATC SPECIAL PROCEDURES

2. RVSM (Operational) Approval: The approval that is issued by the appropriate State authority once an operator has achieved the following:

- RVSM airworthiness approval; and
- State approval of Operations Manual (where applicable) and on-going maintenance procedures.

b. Operators of Canadian-registered aircraft intending to operate in RVSM airspace will be required to show that they meet all the applicable standards in accordance with CARs Part VI and VII. Information on RVSM approval may be obtained from:

Airworthiness Approvals:

Transport Canada Safety and Security

Director, Aircraft Certification (AARD)

Address: Ottawa
 ON
 K1A 0N8

Fax: (613) 996-9178

Operating Standards — Commercial Air Carriers and Private Operators:

Transport Canada Safety and Security

Director, Commercial and Business Aviation (AARX)

Address: Ottawa
 ON
 K1A 0N8

Fax: (613) 954-1602

RVSM Maintenance Programs:

Transport Canada Safety and Security

Director, Aircraft Maintenance and Manufacturing (AARP)

Address: Ottawa
 ON
 K1A 0N8

Fax: (613) 996-9178

12.9.9 Monitoring

a. All operators that operate or intend to operate in airspace where RVSM is applied are required to participate in the RVSM monitoring program. Monitoring prior to the issuance of RVSM operational approval is not a requirement. However, operators should submit monitoring plans to the responsible civil aviation authority to show that they intend to meet the North American RVSM Minimum Monitoring Requirements.

CA 12
ATC SPECIAL PROCEDURES

- b. Ground-based and GPS-based monitoring systems are available to support RVSM operations. Monitoring is a quality control program that enables Transport Canada and other civil aviation authorities to assess the in-service altitude-keeping performance of aircraft and operators.
- c. Ground-based height monitoring systems are located in the vicinity of Ottawa, Ont., and Lethbridge, Alta. Over-flight of ground-based height monitoring systems is transparent to the pilot. Aircraft height-keeping performance monitoring flights using ground based monitoring systems should be flight planned to route within a 30 NM radius of the Ottawa VORTAC, or a 30 NM radius of the Lethbridge VOR/DME.
- d. GPS monitoring unit (GMU) services to conduct a height-keeping performance monitoring flight may be obtained from the following agencies:

CSSI, Inc.

Address: Washington, DC

Tel: (202) 863-2175

E-Mail: monitor@cssiinc.com

Internet: www.cssiinc.com/industries/aviation/reduced-vertical-separation-minimum-rvsm/

ARINC

RVSM Operations Coordinator

Address: Annapolis

Internet: www.rockwellcollins.com/Services_and_Support/Information_Management.aspx

12.9.10 North American Approvals Registry and Monitoring Organization (NAARMO)

- a. The Regional Monitoring Agency for CDA is the NAARMO, located in Atlantic City, NJ, and may be contacted as follows:

William J. Hughes Technical Center

Address: NAS & International Airspace Analysis Branch (ACT-520)
Atlantic City International Airport
Atlantic City
NJ
USA
08405

Fax: (609) 485-5117

CA 12

ATC SPECIAL PROCEDURES

AFTN: N/A

- b. Information on the responsibilities and procedures applicable to the NAARMO may be found on the internet site:

www.faa.gov/air_traffic/separation_standards/naarmo/.

12.9.11 TCAS II/ACAS II RVSM Requirements

Airplanes operating in accordance with CAR 702, 703, 704 and 705 in RVSM airspace must be equipped with TCAS II/ACAS II. The TCAS II/ACAS II must be TSO to TSO-C-119b or later revision (TCAS II software version 7.0). All other TCAS/ACAS-equipped aircraft operating in RVSM airspace should be equipped with software version 7.

12.9.12 Mountain Wave Activity (MWA)

- a. Significant MWA occurs both below and above FL290, which is the floor of RVSM airspace. It often occurs in western Canada and western USA in the vicinity of mountain ranges. It may occur when strong winds blow perpendicular to mountain ranges, resulting in up and down or wave motions in the atmosphere. Wave action can produce altitude excursions and airspeed fluctuations accompanied by only light turbulence. With sufficient amplitude, however, wave action can induce altitude and airspeed fluctuations accompanied by severe turbulence. MWA is difficult to forecast and can be highly localized and short-lived.
- b. Wave activity is not necessarily limited to the vicinity of mountain ranges. Pilots experiencing wave activity anywhere that significantly affects altitude-keeping can follow the guidance provided below.
- c. In-flight indications that the aircraft is being subjected to MWA are:
1. altitude excursions and airspeed fluctuations with or without associated turbulence;
 2. pitch and trim changes required to maintain altitude with accompanying airspeed fluctuations; and
 3. light to severe turbulence depending on the magnitude of the MWA.
- d. TCAS Sensitivity — For both MWA and greater-than-moderate turbulence encounters in RVSM airspace, an additional concern is the sensitivity of collision avoidance systems when one or both aircraft operating in close proximity receive TCAS advisories in response to disruptions in altitude hold capability.
- e. Pre-flight tools — Sources of observed and forecast information that can help the pilot ascertain the possibility of MWA or severe turbulence are: Forecast Winds and Temperatures Aloft (FD), Area Forecast (FA), SIGMETs and PIREPS.

12.9.13 Wake Turbulence

- a. Pilots should be aware of the potential for wake turbulence encounters following Southern Domestic RVSM (SDRVSM) implementation. Experience gained since 1997, however, has shown that such encounters in RVSM airspace are generally moderate or less in magnitude.

CA 12
ATC SPECIAL PROCEDURES

- b. It is anticipated that, in SDRVSM airspace, wake turbulence experience will mirror European RVSM experience gained since January 2002. European authorities have found that reports of wake turbulence encounters had not increased significantly since RVSM implementation (eight versus seven reports in a ten-month period). In addition, they found that reported wake turbulence was generally similar to moderate clear air turbulence.
- c. Pilots should be alert for wake turbulence when operating:
 - 1. in the vicinity of aircraft climbing or descending through their altitude;
 - 2. approximately 12-15 mi. after passing 1000 ft below opposite direction traffic; and
 - 3. approximately 12-15 mi. behind and 1000 ft below same direction traffic.

Figure 12.3 Pilot/Controller Standard Phraseology for RVSM Operations

Message	Phraseology
For a controller to ascertain the RVSM approval status of an aircraft	(call sign) confirm RVSM approval
Pilot indication that flight is RVSM-approved	Affirm RVSM
Pilot will report lack of RVSM approval (Non-RVSM status): a. On the initial call on any frequency in the RVSM airspace; and b. In all requests for flight level changes pertaining to flight levels within the RVSM airspace; and c. In all read-backs to flight level clearances pertaining to flight levels within the RVSM airspace; and d. In read-back of flight level clearances involving climb and descent through RVSM airspace (FL290-410)	Negative RVSM (supplementary information, e.g. "monitoring flight")
Pilot report of one of the following after entry into RVSM airspace; all primary altimeters, automatic altitude control systems or altitude alerters have failed. <i>(This phrase is to be used to convey both the initial indication of RVSM aircraft system failure and on initial contact on all frequencies in RVSM airspace until the problem ceases to exist or the aircraft has exited RVSM airspace)</i>	Unable RVSM Due Equipment
ATC denial of clearance into RVSM airspace	Unable issue clearance into RVSM airspace, maintain FL____.
Pilot reporting inability to maintain cleared flight level due to weather encounters.	Unable RVSM due (state reason) (e.g. turbulence, mountain wave)

CA 12
ATC SPECIAL PROCEDURES

Figure 12.3 Pilot/Controller Standard Phraseology for RVSM Operations (continued)

Message	Phraseology
ATC requesting pilot to confirm that an aircraft has re-gained RVSM-approved status or a pilot is ready to resume RVSM	Confirm able to resume RVSM
Pilot ready to resume RVSM after aircraft system or weather contingency	Ready to resume RVSM

12.9.14 In-Flight Contingencies

- a. The following general procedures are intended as guidance only. Although all possible contingencies cannot be covered, they provide for cases of inability to maintain assigned level due to:

1. weather;
2. aircraft performance; and
3. pressurization failure.

The pilot's judgment should determine the sequence of actions to be taken, taking into account specific circumstances, and ATC shall render all possible assistance.

- b. If an aircraft is unable to continue flight in accordance with its ATC clearance, a revised clearance shall, whenever possible, be obtained prior to initiating any action, using a distress or urgency signal if appropriate. If prior clearance cannot be obtained, an ATC clearance shall be obtained at the earliest possible time. The pilot should take the following actions until a revised ATC clearance is received:

1. establish communications with and alert nearby aircraft by broadcasting, at suitable intervals: flight identification, flight level, aircraft position, (including the ATS route designator or the track code) and intentions on the frequency in use, as well as on frequency 121.5 MHz (or, as a back-up, the inter-pilot air-to-air frequency 123.45);
2. Initiate such action as necessary to ensure safety. If the pilot determines that there is another aircraft at or near the same FL which might conflict, the pilot is expected to adjust the path of the aircraft, as necessary, to avoid conflict.

Figure 12.4 provides pilot guidance on actions to take under certain conditions of aircraft system failure and weather encounters. It also describes the ATC controller actions in these situations. It is recognized that the pilot and controller will use judgement to determine the action most appropriate to any given situation.

CA 12
ATC SPECIAL PROCEDURES

Figure 12.4 Contingency Pilot Actions: Initial Actions

Initial pilot actions when unable to maintain flight level or unsure of aircraft altitude-keeping capability

- Notify ATC and request assistance as detailed below;
- Maintain cleared flight level, if possible, while evaluating the situation;
- Watch for conflicting traffic, both visually and with reference to ACAS/TCAS, if equipped; and
- Alert nearby aircraft by illuminating exterior lights, broadcasting position, flight level and intentions on 121.5 MHz (or as back-up, the inter-pilot air-to-air frequency, 123.45 MHz).

Contingency Pilot Actions: Inability to Maintain Cleared Flight Level Due to Weather

<i>Pilot should:</i>	<i>ATC may be expected to:</i>
– Contact ATC and advise “Unable RVSM Due (state reason)” (e.g. turbulence, mountain wave)	– In radar airspace, where 1000 ft vertical separation exists between two aircraft, and targets appear likely to merge, vector one or both aircraft to establish radar separation until the pilot reports clear of the turbulence
– If not initiated by the controller, and if in radar airspace, request vector clear of traffic at adjacent flight levels	– Provide lateral or longitudinal separation from traffic at adjacent flight levels, traffic-permitting
– Request flight level change or re-route, if desired	– Advise pilot of conflicting traffic
	– Issue flight level change or re-route traffic-permitting

CA 12
ATC SPECIAL PROCEDURES

Contingency Pilot Actions: Report of Mountain Wave Activity (MWA)

<i>Pilot should:</i>	<i>ATC may be expected to:</i>
– Contact ATC and report experiencing MWA	– Advise pilot of conflicting traffic
– If advised of conflicting traffic at adjacent flight levels and the aircraft is experiencing MWA that significantly affects altitude-keeping, request vector to acquire horizontal separation – If so desired, request a flight level change or re-route	– If pilot requests, vector aircraft to achieve horizontal separation, traffic-permitting – In radar airspace, where 1000 ft vertical separation exists between two aircraft, and targets appear likely to merge, vector one or both aircraft to establish radar separation until the pilot reports clear of MWA – Issue flight level change or re-route, traffic-permitting
– Report location and magnitude of MWA to ATC	– Issue PIREP to other aircraft concerned

Contingency Pilot Actions: Wake Turbulence Encounter

<i>Pilot should:</i>	<i>ATC may be expected to:</i>
– Contact ATC and request vector, lateral offset or flight level change	– Issue vector, lateral offset or flight level change, traffic-permitting

Contingency Pilot Actions: Failure of Automatic Altitude Control System, Altitude Alarmer or All Primary Altimeters

<i>Pilot will:</i>	<i>ATC will:</i>
– Contact ATC and advise “Unable RVSM Due Equipment” – Request Clearance out of RVSM airspace, unless operational situation dictates otherwise	– Provide 2000 ft vertical separation or appropriate horizontal separation – Clear aircraft out of RVSM airspace unless operational situation dictates otherwise.

CA 12
ATC SPECIAL PROCEDURES

Contingency Pilot Actions: One Operational Primary Altimeter

<i>Pilot will:</i>	<i>ATC will:</i>
– Cross-check stand-by altimeter – Notify ATC of loss of redundancy, operation with single primary altimeter – If unable to confirm primary altimeter accuracy, follow action for failure of all primary altimeters	– Acknowledge operation with single primary altimeter and monitor progress

12.10 MINIMUM SAFE ALTITUDE WARNING (MSAW)

12.10.1 General

Minimum safe altitude warning (MSAW) is a radar display feature designed to alert controllers to the existence of aircraft operating or predicted to operate at altitudes where separation from terrain cannot be assured. It is used to assist controllers in detecting altitude deviations that could result in controlled flight into terrain (CFIT).

MSAW service is only available in the Vancouver FIR to IFR and CVFR aircraft operating in en route controlled airspace that receive radar service and are in direct communication with the controller. There is a service exclusion zone within a 100 NM radius of CYVR. In addition, MSAW service is not available in control zones and approach/departure corridors.

12.10.2 Procedures

In the event an MSAW is generated, the controller will provide the following information:

- a. TERRAIN WARNING
- b. IMMEDIATE SAFE ALTITUDE [VALUE]
- c. ALTIMETER [VALUE]

12.10.3 Pilot-Initiated Terrain Avoidance Procedure

If the aircraft is equipped with GPWS or TAWS, the flight crew is expected to carry out the appropriate terrain avoidance procedures in response to an on-board alarm. The pilot of a GPWS/TAWS-equipped aircraft should acknowledge receipt of the altimeter and immediate safe altitude information from the controller. The pilot should also advise the controller of the terrain avoidance action being taken when beginning the maneuver or as soon as workload permits.

EXAMPLE:

Pilot: ROGER, INITIATING GPWS/TAWS CLIMB or

ROGER, GPWS/TAWS EQUIPPED

The controller at this point will provide the aircraft with additional terrain-related information, as appropriate.

EXAMPLE:

CA 12
ATC SPECIAL PROCEDURES

ATC: [higher/lower] TERRAIN AHEAD, TO YOUR [left/right] IMMEDIATE SAFE ALTITUDE NOW [altitude]

12.10.4 ATC-Initiated Terrain Avoidance Procedure

After issuing the altimeter and immediate safe altitude information the controller will, if appropriate, provide direction based on the MSAW information received.

EXAMPLE:

ATC: EXPEDITE CLIMB TO SEVEN THOUSAND

In the event that the aircraft is not GPWS/TAWS-equipped or the pilot has not yet received a warning from his/her on-board system, the pilot should request vectors for terrain avoidance assistance as required.

EXAMPLE:

Pilot: REQUEST VECTORS FOR TERRAIN AVOIDANCE or
REQUEST TERRAIN AVOIDANCE INSTRUCTION

Although the prime responsibility to initiate terrain avoidance rests with the pilot, if, in the judgment of the controller, it becomes apparent that the aircraft is in danger of colliding with terrain, the controller may initiate terrain avoidance intervention.

EXAMPLE:

ATC: TURN [left/right] [number of] DEGREES IMMEDIATELY or
CLIMB [altitude] IMMEDIATELY

Once terrain avoidance has been initiated, the pilot will be provided with all additional terrain-related information available.

EXAMPLE:

ATC: [higher/lower] TERRAIN AHEAD, TO YOUR [left/right] IMMEDIATE SAFE ALTITUDE NOW [value]

If, at any time during the procedure, the pilot regains sight of the terrain, visual terrain avoidance should resume and the controller should be advised as soon as practicable.

12.10.5 Assistance to Aircraft in Distress

The digitized terrain contour map component of the MSAW system can be used by the controller independently of the warning function to provide navigational assistance to any aircraft in need. Such aircraft could include radar-identified aircraft that are lost or have encountered icing in mountainous terrain.

Vectoring for terrain avoidance can be provided to aircraft in distress or experiencing an emergency, provided the pilot requests it or the controller suggests it and the pilot concurs.

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

SECTION 13**13.1 GLOBAL NAVIGATION SATELLITE SYSTEM (GNSS)**

The global navigation satellite system (GNSS) is a worldwide position and time determination system that includes one or more satellite constellations, aircraft receivers and system integrity monitoring, alerting, augmented as necessary to support the required navigation performance for the intended operation.

13.2 GLOBAL NAVIGATION SATELLITE SYSTEM (GNSS) CONSTELLATIONS

Currently, there are two complete navigation satellite constellations in orbit: the U.S. global positioning system (GPS) and the Russian global orbiting navigation satellite system (GLONASS). The U.S. and Russia have offered these systems as the basis of a global navigation satellite system (GNSS) that is free of direct user charges. Additional constellations are being developed by the European Union (Galileo), and by China (BeiDou). Instrument flight rules (IFR) certified GNSS receivers manufactured in North America use only the GPS constellation, but plans are underway to expand that ability.

13.2.1 Global Positioning System (GPS)

The GPS constellation was developed by the U.S. military, but since 1996, it has been managed by an executive board, chaired jointly by the departments of Defense and Transportation, that is comprised of representatives from several other departments to ensure that civil users' requirements are considered in the management of the system. Title 10 of the U.S. Code, Section 2281, assigns the Secretary of Defense statutory authority to sustain and operate GPS for military and civil purposes. This statute directs the Secretary of Defense to provide civil GPS service on a continuous, worldwide basis, free of direct user fees.

The design GPS constellation contains 24 GPS satellites, orbiting the earth twice a day at an altitude of 10,900 NM (20,200km). They are arranged in six separate orbital planes, with four satellites in each; this gives complete global coverage. There are approximately 32 operational satellites, however, at any given time, one or more may be decommissioned or be out of service temporarily for maintenance.

All GPS orbits cross the equator at a 55° angle, so it is not possible to see a GPS satellite directly overhead north of 55° N or south of 55° S latitude. This does not affect service in polar areas adversely; in fact, on average, more GPS satellites are visible at high latitudes since receivers can track satellites on the other side of the pole.

GPS positioning is based on precise timing. Each satellite has four atomic clocks on board, guaranteeing an accuracy of one billionth of one second, and broadcasts a digital pseudorandom noise (PRN) code that is repeated every millisecond. All GPS receivers start generating the same code at the same time. Code matching techniques establish the time of arrival difference between the generation of the signal at the satellite and its arrival at the receiver. The speed of the signal is closely approximated by the speed of light, with variations resulting from ionospheric and atmospheric effects modeled or directly measured and applied. The time of arrival difference is converted to a distance, referred to as a pseudorange, by computing the product of the time of arrival

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

difference and the average speed of the signal. The satellites also broadcast orbit information (ephemeris) to permit receivers to calculate the position of the satellites at any instant in time.

Normally, satellites vehicle numbers (SVN) are sequential (ie: SVN 68 was the sixty-eighth satellite launched), but PRN codes are assigned to a position in the constellation, and are numbered PRN 1 to 24 (with a maximum of 32).

A receiver normally needs four pseudoranges to calculate a three-dimensional position and to resolve the time difference between receiver and satellite clocks. In addition to position and time, GPS receivers can also calculate velocity-both speed and direction of motion.

GPS accuracy depends on transit time and signal propagation speed to compute pseudoranges. Therefore, accurate satellite clocks, broadcast orbits, and computation of delays as the signals pass through the ionosphere are critical. The ionosphere, which is a zone of charged particles several hundred kilometers above the earth, causes signal delays that vary from day to night and by solar activity. Current receivers contain a model of the nominal day/night delay, but this model does not account for variable solar activity. For applications requiring high accuracy, GPS needs an augmentation system to correct the computed transit time to compensate for this delay.

Another key to GPS accuracy is the relative position of satellites in the sky, or satellite geometry. When satellites are widely spread, geometry and accuracy are better. If satellites are clustered in a small area of the sky, geometry and accuracy are worse. Currently, GPS horizontal and vertical positions are accurate to 6m and 8m, respectively, 95% of the time.

The GPS satellite constellation is operated by the U.S. Air Force from a control center at Schriever Air Force Base in Colorado. A global network of monitor and uplink stations relays information about the satellites to the control center and sends messages, when required, to the satellites.

If a problem is detected with a satellite, it is commanded to send an “unhealthy” status indication, causing receivers to drop it from the position solution. Since detection and resolution of a problem take time, and this delay is unacceptable in aviation operations, augmentation systems are used to provide the level of integrity required by aviation.

The GPS constellation status is available at <https://www.navcen.uscg.gov/?Do=constellationStatus>.

13.2.2 Global Orbiting Navigation Satellite System (GLONASS)

GLONASS is a global satellite constellation, operated by the Russian Aerospace Defence Forces, that provides real-time position and velocity determination for military and civilian users. The satellites are located at an altitude of 19,100km and at an inclination of the orbital planes of 64.8° to the equator.

The GLONASS constellation status is available at <https://www.glonass-iac.ru/en/sostavOG/>.

13.2.3 Galileo Navigation Satellite System

Galileo is Europe's GNSS constellation, which will provide a highly accurate, guaranteed global positioning service under civilian control. The fully deployed Galileo system will consist of 24 operational satellites plus six in-orbit spares, positioned in three circular medium earth orbit

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

(MEO) planes at an altitude of 23,222km, and at an inclination of the orbital planes of 56° to the equator.

The Galileo constellation status is available at <https://www.gsc-europa.eu/system-status/Constellation-Information>.

13.2.4 BeiDou Navigation Satellite System

BeiDou is the Chinese navigation satellite system. It consists of two separate satellite constellations: a limited test system that has been operating since 2000 and a full-scale global navigation system that is currently under construction.

The BeiDou constellation status is available at www.csno-tarc.cn/en/.

13.3 AUGMENTATION SYSTEMS

Augmentation of the global positioning system (GPS) constellation or the global orbiting navigation satellite system (GLONASS) constellation is required to meet the accuracy, integrity, continuity and availability requirements for aviation. There are currently three types of augmentation:

- a. aircraft-based augmentation system (ABAS);
- b. satellite-based augmentation system (SBAS); and
- c. ground-based augmentation system (GBAS).

13.3.1 Aircraft-Based Augmentation System (ABAS)

RAIM and fault detection and exclusion (FDE) functions in current IFR-certified avionics are considered ABAS. RAIM can provide the integrity for the enroute, terminal, and non-precision approach phases of flight. FDE improves the continuity of operation in the event of a satellite failure and can support primary-means oceanic operations.

RAIM uses extra satellites in view to compare solutions and detect problems. It usually takes four satellites to compute a navigation solution, and a minimum of five for RAIM to function. The availability of RAIM is a function of the number of visible satellites and their geometry. It is complicated by the movement of satellites relative to a coverage area and temporary satellite outages resulting from scheduled maintenance or failures.

If the number of satellites in view and their geometry do not support the applicable alert limit (2 NM enroute, 1 NM terminal and 0.3 NM non-precision approach), RAIM is unable to guarantee the integrity of the position solution. (Note that this does not imply a satellite malfunction.) In this case, the RAIM function in the avionics will alert the pilot, but will continue providing a navigation solution. Except in cases of emergency, pilots must discontinue using GNSS for IFR navigation when such an alert occurs.

A second type of RAIM alert occurs when the avionics detects a satellite range error (typically caused by a satellite malfunction) that may cause an accuracy degradation that exceeds the alert limit for the current phase of flight. When this occurs, the avionics alerts the pilot and denies navigation guidance by displaying red flags on the HSI or course deviation indicator (CDI). Continued flight using GNSS is then not possible until the satellite is flagged as unhealthy by the control center, or normal satellite operation is restored.

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

Some avionics go beyond basic RAIM by having an FDE feature that allows the avionics to detect which satellite is faulty, and then to exclude it from the navigation solution. FDE requires a minimum of six satellites with good geometry to function. It has the advantage of allowing continued navigation in the presence of a satellite malfunction.

Most first generation avionics do not have FDE and were designed when GPS had a feature called selective availability (SA) that deliberately degraded accuracy. SA has since been discontinued, and new generation SBAS-capable receivers (TSO C145a/C146a) account for SA being terminated. These receivers experience a higher RAIM availability, even in the absence of SBAS messages, and also have FDE capability.

For avionics that cannot take advantage of SA being discontinued, average RAIM availability is 99.99% for enroute and 99.7% for non-precision approach operations for a 24-satellite GPS constellation. FDE availability ranges from 99.8% for enroute to 89.5% for non-precision approach. Avionics that can take advantage of SA having been discontinued have virtually 100% availability of RAIM for enroute and 99.998% for non-precision approach; FDE availability ranges from 99.92% for enroute to 99.1% for non-precision approach. These figures have been computed for mid-latitudes, and are dependent on user position and also on which satellites are operational at any given time. RAIM and FDE availability is typically even better at high latitudes, since the receiver is able to track satellites on the other side of the North Pole.

The level of RAIM or FDE availability for a certain airspace at a certain time is determined by an analysis of satellite geometry, rather than signal measurement. This is why it can be predicted by receivers or with PC-based computer software. The difference between the two methods is that the receivers use the current constellation in their calculations while the PC software can use a constellation definition that takes into account scheduled satellite outages.

Most TSO C129a avionics also accept signals from an aircraft altitude encoder. This is called baro-aiding, and it essentially reduces the number of satellites required by one, thus further increasing the availability of RAIM and providing an additional measure of tolerance to satellite failures.

With proper integration, IRS can augment/enhance GNSS navigation. This system allows “coasting” through periods of low availability.

13.3.2 Satellite-Based Augmentation System (SBAS)

SBAS uses a network of ground-based reference stations that monitor navigation satellite signals and relay data to master stations, which assess signal validity and compute error corrections. The master stations generate two primary types of messages: integrity, and range corrections. These are broadcast to SBAS-capable GNSS receivers via GEO satellites in fixed orbital positions over the equator. The SBAS GEO satellites also serve as additional sources of navigation ranging signals.

The integrity messages provide a direct validation of each navigation satellite’s signal. This function is similar to RAIM, except that the additional satellites required for RAIM are not necessary when SBAS integrity messages are used. The integrity messages are available wherever the GEO satellite signal can be received.

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

The range corrections contain estimates of the errors introduced into the range measurements as a result of ionospheric delays, and satellite ephemeris (orbit) and clock errors. Ionospheric delay terms are critical for correction messages, and are also the most challenging to characterize. First, each reference station measures the ionospheric delay for each visible satellite. These observations are sent to the master station, where they are combined, and used to generate a model of the ionosphere, which is then transmitted to the receivers via the GEO satellite. The accuracy of the model is dependent on the number and placement of the reference stations providing observations of ionospheric delays.

By compensating for these errors, SBAS-capable GNSS receivers can compute the position of the aircraft with the accuracy necessary to support flight operations with vertical guidance. Vertical guidance provides safer stabilized approaches and transition to visual for landing. This represents one of the principal benefits from SBAS service. The other is lower approach minima at certain airports, as a result of greater lateral accuracy.

The first SBAS, the U.S. FAA's WAAS, was commissioned in 2003. Europe has built a compatible system called EGNOS (European Geostationary Navigation Overlay Service) which was approved for aviation use in August 2010. Japan and India also have similar systems to augment GNSS: MSAS (MTSAT Satellite-Based Augmentation System) and GAGAN (GPS and GEO Augmented Navigation), respectively.

WAAS messages are currently being broadcast by three geostationary satellites located on the equator at 107.3°W, 116.8°W and 133°W.

13.3.3 Ground-Based Augmentation System (GBAS)

GBAS, also known as LAAS, sends corrections directly to GBAS-capable receivers from a ground station at an airport.

GPS receivers with antennas at surveyed locations provide measurements used to generate and broadcast pseudorange corrections. Aircraft receivers use the corrections for increased accuracy, while a monitor function in the ground station assures the integrity of the broadcast. GBAS provides service over a limited area, typically within 30 NM of the ground station.

GBAS is not yet available in Canada.

13.4 DOMESTIC IFR APPROVAL TO USE GNSS AND SBAS

The Global Navigation Satellite System (GNSS) and satellite-based augmentation system (SBAS) approved for instrument flight rules (IFR) use in Canada.

CA 13
GLOBAL NAVIGATION SATELLITE SYSTEM

Global Navigation Satellite System

Element	Name	Nominal Service Area	Operating Authority	Remarks
Constellation	Global Orbiting Navigation Satellite System (GLONASS)	Canadian Domestic Airspace	Ministry of Defence of the Russian Federation	Enroute, terminal, and non-precision approaches (NPA).
Constellation	Global Positioning System (GPS)	Canadian Domestic Airspace	US Department of Defense	Enroute, terminal, and non-precision approaches (NPA).
Satellite Based Augmentation System	European Geostationary Navigation Overlay Service (EGNOS)	Eastern Canada: Thunder Bay to St. John's to approximately N50°	European Space Agency (ESA)	Augmentation to GNSS for enroute, terminal, and NPA.
Satellite Based Augmentation System	Wide Area Augmentation System (WAAS)	Canadian Domestic Airspace to approximately N70° (subject to visibility of at least one WAAS geostationary satellite (GEO))	US Federal Aviation Administration (FAA)	Augmentation to GNSS for enroute, terminal, NPA, lateral and vertical navigation (LNAV/VNAV) and lateral precision with vertical guidance (LPV) approaches.

GNSS capability may be provided by a panel-mount receiver, or an FMS that uses the appropriate sensor.

Avionics are required to meet appropriate equipment standards, and equally important, the avionics installation must be approved by Transport Canada to ensure proper avionics integration and display.

Hand-held and other VFR receivers do not support integrity monitoring, nor do they comply with other certification requirements; therefore, they cannot be used for IFR operations.

Holders of air operator certificates (AOCs) issued under Part VII of the CARs, and private operator certificates issued under Subpart 604 of the CARs, are required to be authorized to conduct GNSS instrument approach operations in IMC.

13.4.1 Domestic Enroute and Terminal Operations

In practice, pilots can use GNSS for guidance most of the time. If an integrity alert occurs while enroute, the pilot can then continue by using traditional aids, diverting if necessary from the direct routing, notifying ATS of any changes to the flight and obtaining a new clearance, as required.

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

When using GNSS to maintain a track in terminal operations, the avionics shall be in terminal mode and/or the course deviation indicator (CDI) shall be set to terminal sensitivity. (Most avionics set the mode and sensitivity automatically within 30 NM of the destination airport, or when an arrival procedure is loaded.)

When using GNSS to navigate along VHF/UHF or LF/MF airways, ground-based NAVAID reception is not an issue. This means that pilots using GNSS for navigation can file or request an altitude below the MEA, but at or above the MOCA, to avoid icing, optimize cruise altitude, or in an emergency. However, an ATS clearance to fly at a below-MEA altitude could be dependent on issues such as radio communication reception and the base of controlled airspace. In the rare case of a RAIM alert while enroute below the MEA, and out of range of the NAVAID, pilots should advise ATS and climb to continue the flight using alternate means of navigation.

GNSS avionics typically display the distance to the next waypoint. To ensure proper separation between aircraft, a controller may request the distance from a waypoint that is not the currently-active waypoint in the avionics; it may even be behind the aircraft. Pilots must be able to obtain this information quickly from the avionics. Techniques vary by manufacturer, so pilots should ensure familiarity with this function.

At times outside radar coverage, pilots may be cleared by ATS to a position defined by a latitude and longitude. As these are usually outside the range of traditional NAVAIDs, there is no means to cross check that the coordinates have been entered accurately. Pilots must be particularly careful to verify that the coordinates are correct.

13.4.2 GNSS-Based RNAV Approach Procedures

Prior to the advent of GNSS, only two types of approach and landing operations were defined: precision approach (PA) and non-precision approach (NPA). Definitions have now been added for approach procedures with vertical guidance (APV), to cover approaches that use lateral and vertical guidance, but that do not meet the requirements established for precision approaches.

GNSS-based approaches are charted as “RNAV (GNSS) RWY XX.” The “(GNSS)” before the runway identification indicates that GNSS must be used for guidance. Pilots and controllers shall use the prefix “RNAV” in radio communications (e.g. “CLEARED TO THE VANCOUVER AIRPORT RNAV RUNWAY ZERO FOUR APPROACH”).

GNSS-based RNAV approaches are designed to take full advantage of GNSS capabilities. A series of waypoints in a “T” or “Y” pattern eliminates the need for a procedure turn. The accuracy of GNSS may result in lower minima and increased capacity at the airport. Because GNSS is not dependent on the location of a ground-based aid, straight-in approaches are possible for most runway ends at an airport.

In Canada, RNAV (GNSS) approach charts may depict up to five sets of minima:

- LPV (localizer performance with vertical guidance);
- LP (localizer performance);
- LNAV/VNAV (lateral/vertical navigation);
- LNAV (lateral navigation); and

CA 13
GLOBAL NAVIGATION SATELLITE SYSTEM

– CIRCLING.

The LP and LNAV minima indicate a NPA, while the LNAV/VNAV and LPV minima refer to APV approaches (RNAV approaches with vertical guidance). However, the actual terms “NPA” and “APV” do not appear on the charts because they are approach categories not related to specific procedure design criteria. In Canada, the depiction of the five sets of minima is similar to the way that an ILS approach may show landing minima for ILS, LOC and CIRCLING.

The approach chart may indicate a WAAS channel number. This is used for certain types of avionics, and permits the approach to be loaded by entering the number shown.

All approaches must be retrieved from the avionics database, and that database must be current. While it is sometimes acceptable to use pilot-generated waypoints enroute, it is not permitted for approach procedures.

13.4.2.1 RNAV Approaches with Lateral Guidance Only

Avionics for LNAV approaches do not define a vertical path through space; as such, each approach segment has a minimum altitude below which the pilot may not descend.

GPS (TSO C129/C129a Class A1, B1, B3, C1 or C3) and WAAS (TSO C145a/C146a, any class) avionics are both able to provide the lateral guidance required for these approaches.

Without vertical guidance, pilots are required to remain at or above the MDA unless a visual transition to landing can be accomplished, or to conduct a missed approach at the missed approach waypoint (MAWP), typically located over the runway threshold.

WAAS and some GPS TSO C129/C129a avionics may provide advisory vertical guidance when flying approaches without LNAV/VNAV or LPV minima. It is important to recognize that this guidance is advisory only and the pilot is responsible for respecting the minimum altitude for each segment until a visual transition to land is commenced.

Pilots using TSO C129/C129a avionics should use the RAIM prediction feature (including known satellite outages obtained by NOTAM at KGPS) to ensure that approach-level RAIM will be supported at the destination or alternate airport for the ETA (+/- 15 min). This should be done before takeoff, and again prior to commencing a GNSS-based approach. If approach-level RAIM is not expected to be available, pilots should advise ATS as soon as practicable and state their intentions (e.g. delay the approach, fly another type of approach, proceed to alternate).

13.4.2.2 Vertical Guidance on RNAV Approaches

LNAV/VNAV and LPV describe approaches with vertical guidance. These will deliver the safety benefits of a stabilized approach and, in many cases, will improve airport accessibility.

Aircraft with TSO C145a/C146a (WAAS Class 2 or 3) or TSO C115b (multi-sensor FMS) avionics, may fly RNAV (GNSS) approaches to LNAV/VNAV minima with vertical guidance in a similar manner to the way they fly an ILS approach: with both a lateral course deviation indicator (CDI) and a vertical deviation indicator (VDI). The lateral guidance must be based on GPS or WAAS. The vertical guidance may be based on WAAS, or on barometric inputs (Baro VNAV), depending on the approach and the aircraft equipage.

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

Aircraft with WAAS Class 3 avionics may fly RNAV (GNSS) approaches to LPV minima in a similar manner. In this case, both the lateral and vertical guidance are based on WAAS.

The nominal final approach course vertical flight path angle for LNAV/VNAV and LPV approaches is 3°, avoiding the step-down minimum altitudes associated with traditional non-precision approaches.

The LNAV/VNAV and LPV minima depict a decision altitude (DA), which requires the pilot to initiate a missed approach at the DA if the visual reference to continue the approach has not been established.

13.4.2.3 *Area Navigation (RNAV) Approaches with Vertical Guidance Based on Barometric Vertical Navigation (Baro VNAV)*

Multi-sensor FMSs meeting TSO C115b have been certified since the late 1980's to provide guidance for a stabilized final approach segment while flying NPAs. The vertical guidance for these systems has been derived from a barometric altitude input; hence, these approaches are known as Baro VNAV approaches. This equipment has typically only been installed on transport category airplanes. The information provided by these systems is advisory only, and pilots are required to respect all minimum altitudes, including step-down altitudes, since NPAs are not specifically designed to take advantage of Baro VNAV capability.

With the publication in Canada of RNAV (GNSS) approaches with vertical guidance, suitably-equipped aircraft may fly Baro VNAV approaches to the LNAV/VNAV minima published on these approach plates. The standard for equipment is a multisensor FMS that meets TSO-C115b and is certified in accordance with FAA AC 20-138C or equivalent. The FMS must use GNSS sensor input, but does not require a WAAS-capable receiver to fly to LNAV/VNAV minima. Pilots must note that the vertical path defined by Baro VNAV is affected by altimeter setting errors. For this reason, Baro VNAV is not authorized unless a local field altimeter setting is available.

Non-standard atmospheric conditions, particularly temperature, also induce errors in the Baro VNAV vertical path. A nominal 3° glide path will be steeper at warmer temperatures and shallower at lower temperatures. To compensate for these temperature effects, some avionics allow input of the temperature at the airport and apply temperature compensation to the vertical path angle so that the Baro VNAV vertical path is not biased as a function of temperature. Unfortunately, not all systems have similar capabilities to compensate for temperature effects, and pilots need to understand their system's capabilities.

When temperature compensation is not or cannot be applied through the FMS, pilots shall refer to a temperature limit, referred to as TLim, published on the approach chart. This limiting temperature protects a Baro VNAV's final segment vertical path only (it does not protect any of the published minimum IFR altitudes on the chart). Below this temperature, the uncompensated vertical path generated by the FMS will not provide the required obstacle protection. Therefore, when the temperature is below the published TLim, an aircraft with an uncompensated Baro VNAV system shall not fly an RNAV approach to LNAV/VNAV minima. TLim will be a function of the reduced obstacle clearance resulting from flying an uncompensated VPA and will vary from approach to approach. For avionics systems that have the capability to correctly adjust the VPA for tempera-

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

ture deviations, the published TLim does not apply if the pilot enables the temperature compensation.

In short, regardless of whether or not the FMS (or other automated means) provides temperature compensation of the vertical path, and whether or not the actual reported airport temperature is within the temperature limit for the procedure, pilots are responsible for correcting the temperature of all minimum published IFR altitudes on the approach, including the DA.

13.4.2.4 *Area Navigation (RNAV) Approaches with Vertical Guidance Based on Wide Area Augmentation System (WAAS)*

RNAV (GNSS) approaches with vertical guidance based on WAAS require a Class 2 or 3 (for LNAV/VNAV minima) or Class 3 (for LPV minima) TSO C145a WAAS receiver, or a TSO C146a sensor interfaced to appropriate avionics.

RNAV (GNSS) approaches with vertical guidance based on WAAS are entirely dependent on the WAAS signal. WAAS meets essentially the same navigation performance requirements (accuracy, integrity and continuity) as ILS, and pilots can expect that guidance will be similar to that provided by an ILS, with some improvement in signal stability over ILS.

WAAS avionics continuously calculate integrity levels during an approach and will provide a message to the crew if alert limits are exceeded, analogous to ILS monitors that shut down an ILS signal when its accuracy does not meet the required tolerances.

Although the WAAS integrity monitor is very reliable, good airmanship nevertheless dictates that pilots verify the final approach waypoint (FAWP) crossing altitude depicted on approach plates with LNAV/VNAV and LPV minima, in the same way that the beacon crossing altitude is checked when flying an ILS approach. Large altitude deviations could be an indication of a database error or otherwise undetectable incorrect signal.

13.5 FLIGHT PLANNING

NOTAM on ground-based NAVAID outages are of direct use to pilots because if a NAVAID is not functioning, the related service is not available. With GPS and WAAS, the knowledge of a satellite outage does not equate to a direct knowledge of service availability. The procedures for determining service availability are different for GPS (TSO C129/C129a) and WAAS (TSO C145a/C146a) avionics, and are explained in the next sections.

13.5.1 GPS NOTAM

NOTE: This section is applicable only to operators using TSO C129/C129a avionics.

Research has shown minor differences among avionics' computations of RAIM availability, making it impractical to develop a GPS RAIM NOTAM system that will work reliably for all receivers. Because of this, and since the IFR GPS approval requires aircraft to be equipped with traditional avionics to be used when RAIM is unavailable, NOTAM information on GPS RAIM availability is not provided in Canada. Canadian flight information centers (FIC) can supply NOTAM on GPS satellite outages by querying the international NOTAM identifier KGPS. (This information is also available at <https://www.notams.faa.gov>.) The availability of RAIM can then be computed from the satellite availability information by entering the expected outages into PC-based RAIM

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

prediction software provided by some avionics manufacturers or through direct entry into GNSS receiver or FMS computers that support this function.

GNSS avionics also contain such a model, and this allows pilots to determine if approach-level RAIM will be supported (available) upon arrival at destination or an alternate. The calculation typically uses current information, broadcast by the satellites, identifying which satellites are in service at that time. However, unlike the software that is based on the NOTAM data, this prediction does not take into account scheduled satellite outages.

Operators using TSO C129/C129a avionics who wish to take advantage of an RNAV (GNSS) approach when specifying a destination or alternate airport must check KGPS NOTAM to verify the status of the constellation.

13.5.2 Wide Area Augmentation System (WAAS) NOTAM

A NOTAM will be issued whenever the FAA advises NAV CANADA that LPV, LP and WAAS-based LNAV/VNAV service is unavailable for a period of more than 15 min. The NOTAM is issued for the FIR and will read either:

- a. LPV, LP AND WAAS-BASED LNAV/VNAV APCH NOT AVBL (and may include a description of the affected area, if WAAS messages issued by a particular WAAS satellite are not available); or
- b. WAAS UNMONITORED (indicating that WAAS messages may not be available across the entire service area).

Pilots should flight plan based on the assumption that the services referred to in a NOTAM will not be available. However, once they arrive at the airport, they may discover that a service is in fact available, in which case they may use the approach safely if they so choose.

When LPV, LP and WAAS-based LNAV/VNAV are not available, pilots may fly the LNAV procedure to the published MDA as this will almost always be available to pilots using WAAS avionics. Since LNAV procedures will be used when LPV and LNAV/VNAV are not available, pilots should ensure that they maintain their skills in flying these approaches.

NOTE: WAAS NOTAM information is not applicable to users of TSO C129a avionics.

NOTAM examples can be found in the *Canadian NOTAM Operating Procedures*, available here: <https://www.navcanada.ca/en/aeronautical-information/operational-guides.aspx>.

13.5.3 Negative W Notation

Normally, WAAS-based approaches will only be designed and published where the nominal availability of the required service is greater than 99%.

However, there may be airports on the fringe of WAAS coverage areas, for which an LPV, LP, or WAAS-based LNAV/VNAV approach is published because of a local demand by operators. In the event that an approach is located in a region of marginal WAAS availability, pilots will be alerted to this fact by a negative “W” (white on a black background) on the approach plate.

Pilots should flight plan as though LPV, LP and WAAS-based LNAV/VNAV will not be available at these airports; however, if the service is available, it may be used safely at the pilot's discretion.

CA 13
GLOBAL NAVIGATION SATELLITE SYSTEM

13.5.4 Space Weather

The source of space weather is the sun, which releases streams of charged particles made up of energized electrons and protons.

Two types of solar phenomena can have a major impact on GNSS: coronal mass ejections (CMEs) and coronal holes. Coronal mass ejections are gigantic amounts of electrified gas or plasma launched into space that can have a major influence, typically reaching the Earth within 1–3 days. Coronal holes are regions of open magnetic field lines where high-speed streams of plasma can flow out from the sun. If conditions are right when these particles reach the Earth, geomagnetic storms can occur.

At the Earth's surface, geomagnetic storms are characterized by a K-level index that ranges from 0–9. Storms having little effect would range from 0–3, while those with moderate effects would be 4–7, and strong storms with a lot of impact would be > 7. The Canadian Space Weather Forecast Centre (CSWFC) monitors, analyzes and forecasts space weather. Based on solar observations, it can predict when the particles will reach the Earth, and forecast the expected geomagnetic activity that will result. More detailed measurements are made using space weather monitoring satellites, which provide information approximately 30 min before the particles reach the Earth.

Canada has three zones of geomagnetic activity: the polar cap, the auroral zone and the subauroral zone. The highest geomagnetic activity and greatest disturbances are observed in the auroral zone. Changes in electron density, due to space weather activity, can change the speed at which radio waves travel, introducing a “propagation delay” in the GNSS signal through the ionosphere. The propagation delay can vary from minute to minute, and these intervals of rapid change can sometimes last for several hours, especially in the polar and auroral regions. Changing propagation delays cause errors in the determination of the range.

ABAS, SBAS and GBAS use different techniques to correct for ionospheric delays. ABAS uses simple models implemented in the receiver software that are adequate for enroute navigation through non-precision approach phases of flight, but are not adequate for any type of approach during which vertical guidance is provided. SBAS provides ionospheric delay corrections derived from measurements at a set of reference stations distributed over a wide area. GBAS provides corrections for the combined effects of various sources of ranging errors, including ionospheric delays. The corrections provided by SBAS and GBAS are much more accurate than those calculated by ABAS, because they are derived in real-time from actual measurements, and are therefore adequate for approach procedures with vertical guidance.

GNSS provides navigation either using unaugmented GNSS and RAIM or FDE, or using SBAS corrections. The availability and continuity of GNSS enroute and NPA services are very robust against ionospheric delays caused by geomagnetic storms. This robustness is primarily due to the relatively wide alert limits associated with enroute and non-precision approach operations.

SBAS augmentation makes APV possible by ensuring real-time monitoring of core constellation satellites and ionospheric delays. APV operations require accurate ionospheric corrections, as well as relatively narrow integrity bounds, and these bounds may be widened during periods when the ionosphere is severely disturbed, in order to account for the increased variability of ionospheric delays, while ensuring the integrity of the position solutions for all users. APV service is very robust in mid- and high-latitude regions, and losses of service due to ionospheric effects are

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

expected to occur less than 1% of the time. Interruptions of APV service may occur during severe geomagnetic storms and affect portions of the service area for short periods of time. In rare cases, extremely severe geomagnetic storms may even cause temporary loss of APV service over large portions of the SBAS service area for several hours. During pre-flight planning, pilots can consult Canadian Space Weather Forecast Centre products to determine if APV service for their flight may be affected. See: www.spaceweather.gc.ca/index-en.php.

13.6 IFR FLIGHT PLAN EQUIPMENT SUFFIXES

On an IFR flight plan, the letter “G” in item 10 (Equipment and capabilities) indicates that the aircraft has IFR-approved GPS or WAAS avionics, and can therefore be cleared by ATS on direct routings while enroute, in terminal areas, and for GNSS-based approaches.

13.7 AVIONICS DATABASES

GNSS avionics used for IFR flight require an electronic database that can be updated, normally on 28- or 56-day cycles. The updating service is usually purchased under subscription from avionics manufacturers or database suppliers.

Database errors do occur, and should be reported to the avionics database supplier. Jeppesen accepts e-mailed database reports at navdatatechsupport@jeppesen.com. It is good practice to verify that retrieved data is correct, and it is mandatory to do so for approach data. Verification can be accomplished either by checking waypoint co-ordinates or by checking bearings and distances between waypoints against charts.

13.8 USE OF GNSS IN LIEU OF GROUND-BASED AIDS

GNSS may be used in lieu of DME during departure/enroute/terminal/approach operations; it may be used in lieu of conventional (VOR and NDB) for departure/enroute/terminal operations provided the following conditions are met:

- a. An integrity alert is not displayed;
- b. Fixes that are part of a terminal instrument procedure are named, charted and retrieved from a current navigation database; and
- c. When the air traffic service (ATS) requests a position based on a distance from a DME facility for separation purposes, reported GNSS distance from the same DME facility may be used by stating the distance in miles and the DME facility name (e.g. “30 MILES FROM SUMSPOT VOR”, vice “30 DME FROM SUMSPOT VOR”).

GNSS may not be used in lieu of ground-based aids for:

- VOR and NDB final approach segment LNAV guidance on VOR- or NDB- instrument approach procedures; or
- LOC LNAV guidance.

Examples of GNSS substitution include:

CA 13 GLOBAL NAVIGATION SATELLITE SYSTEM

Examples of GNSS Substitution

Approach Type	Failed Item	GNSS Substitution Allowed
NDB RWY 08R	aircraft ADF* or approach NDB	No
NDB/DME RWY 08R	aircraft DME or approach DME	Yes
VOR RWY 09	aircraft VHF navigation or approach VOR	No
VOR/DME RWY 09	aircraft DME or approach DME	Yes
ILS Y RWY 16	aircraft ADF*/DME or missed approach NAVAID	Yes

*ADF = automatic direction finder

13.9 AREA NAVIGATION (RNAV) APPROACHES AT ALTERNATE AIRPORTS

Pilots may take credit for an area navigation (RNAV) approach at an alternate airport as outlined in the *Canada Air Pilot* (CAP) (not published herein).

Taking credit for RNAV approaches at an alternate airport for IFR flight plan filing purposes is possible because the availability of RAIM or WAAS integrity to support non-precision approaches is normally very high. However, when satellites are out of service, availability could decrease. Consequently, it is necessary to determine satellite status to ensure that the necessary level of integrity will be available at the ETA at the alternate. The procedures for this are explained in the next two subsections.

13.9.1 GNSS Approaches at Alternate Airports — GPS (TSO C129/C129a) Avionics

The status of the GPS constellation may be obtained through the FAA by contacting a NAV CANADA FIC and requesting the international NOTAM file KGPS.

A procedure that meets the requirement to ensure that approach-level RAIM will be available for TSO C129/C129a avionics is as follows.

- a. Determine the ETA at the proposed airport.
- b. Check GPS NOTAM (KGPS) file for a period of 60 min before and after the ETA. If not more than one satellite outage is predicted during that period, then this procedure is satisfied. If two or more satellites are anticipated to be unserviceable during the ETA +/-60-min period, then it is necessary to determine if approach-level RAIM will be available, taking into account the reduced availability resulting from the outages. This may be accomplished by using commercially-available dispatch RAIM prediction software, acquiring a current almanac, and manually deselecting those satellites for the times described in the NOTAM.

The RAIM availability requirement is satisfied if the resulting prediction indicates that RAIM will be unavailable for a total of 15 min or less during the ETA +/-60-min period.

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

It may be possible to change the alternate or adjust the departure time (and hence the ETA) and re-run the prediction to find a time for which the required RAIM availability is achieved, or simply to find a time when fewer than two satellite outages are predicted.

13.9.2 GNSS Approaches — WAAS Avionics

Operators using WAAS avionics (TSO-C145a/C146a) can verify that an approach is expected to be available by:

- a. checking NOTAM that apply to the FIR to ensure that no widespread WAAS outages have occurred, and then
- b. checking the WAAS horizontal and vertical service status, available at <http://www.nstb.tc.faa.gov/index.htm>, to predict if the desired approach line of minima is available given the current ionospheric conditions.

In the event of a widespread outage of WAAS, poor WAAS horizontal or vertical performance due to current ionospheric conditions, or an airport outside the GEO coverage area, the pilot may need to determine if approach-level RAIM, as computed by a WAAS receiver, will be available. In this case, the pilot may use the procedure described in the preceding section for TSO C129/ C129a avionics. This will provide a safe, although conservative, indication of the availability of LNAV.

13.10 GNSS VULNERABILITY — INTERFERENCE AND ANOMALY REPORTING

GNSS is used in many applications: financial, security and tracking, transportation, agriculture, communications, weather prediction, scientific research, etc. Because it is used for such a wide range of civilian purposes, when somebody wishes to disable one GNSS-based system, their actions can also disrupt other, unrelated systems. Jamming, directed at non-aviation users, could affect aircraft operations. Over the past few years, Industry Canada has encountered several cases of illegal importation, manufacturing, distribution, offering for sale, possession and use of radio communication jamming devices, all of which are prohibited under the *Radiocommunication Act*. Many jamming devices are manufactured for the purpose of disrupting the functioning of GNSS receivers, cellular networks and low-power communication devices, such as cordless telephones and Wi-Fi networks. Of primary concern is the proliferation of radio communication jammers designed to defeat vehicle tracking and fee-collecting systems. Depending on signal strength, these jammers can also prevent communication related to 9-1-1 and emergency services, while inadvertently and unknowingly in most cases, inhibiting aircraft in the vicinity overhead from receiving GNSS signals.

In the event of suspected interference or other problems with GNSS, pilots should advise ATS, and, if necessary, revert to using traditional aids for navigation. Pilots are also requested to complete a GNSS Anomaly Report Form, available at www.navcanada.ca/EN/products-and-services/Pages/Post-Flight-Reports.aspx, or equivalent, in order to assist in the identification and elimination of sources of interference or degradation of the navigation signal.

CA 13

GLOBAL NAVIGATION SATELLITE SYSTEM

13.11 PROPER USE OF GNSS

GNSS offers a great opportunity to improve aviation safety and efficiency. Many pilots are already benefiting from the advantages of GNSS as a principal navigation tool for IFR flight or for VFR operations. To ensure safety, pilots must use GNSS properly. Here are some safety tips:

- Use only IFR-certified avionics for IFR flights because hand-held and panel-mount VFR do not provide the integrity needed for IFR operations;
- For IFR flight, a valid database shall be used for approach—a new one is required every 28 or 56 days;
- Verify that all procedures that could be required are present in the database prior to flight to remote or small airports—data storage limitations have resulted in some manufactures omitting certain data from the avionics database;
- Do not become an approach designers—approach designers require special training and specific tools, and there are many levels of validation before an approach is commissioned. Furthermore, the receiver RAIM level and course deviation indicator (CDI) sensitivity will not be appropriate if an approach is not retrieved from the avionics database;
- Never fly below published minimum altitudes while in instrument conditions. Accidents have resulted from pilots relying too much on the accuracy of GNSS;
- use VFR GNSS receivers only to supplement map reading in visual conditions, not as a replacement for current charts;
- Position hand-held receivers and related cables carefully in the cockpit to avoid the potential for electromagnetic interference (EMI), and to avoid interfering with aircraft controls. Hand-held units with valid databases could be useful in an emergency if IFR units failed; and
- Resist the urge to fly into marginal weather when navigating VFR. The risk of becoming lost is small when using GNSS, but the risk of controlled flight into terrain (CFIT) increases in low visibility. VFR charts must also be current and updated from applicable NOTAMs, and should be the primary reference for avoiding alert areas, etc. Some VFR receivers display these areas, but there is no guarantee that the presentation is correct, because there is no standard for such depictions.

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

15 ATC ANNEX — CANADIAN AVIATION REGULATIONS (CARs)**15.1 GENERAL**

This annex contains those Canadian Aviation Regulations (CARs) that relate to the subject matter of this chapter, but may not have been incorporated, in full or in part, in the chapter text.

15.2 CANADIAN AVIATION REGULATIONS**Reckless or Negligent Operation of Aircraft***CAR 602.01*

No person shall operate an aircraft in such a reckless or negligent manner as to endanger or be likely to endanger the life or property of any person.

Fitness of Flight Crew Members*CAR 602.02*

An operator of an aircraft shall not require any person to act as a flight crew member or to carry out a preflight duty, and a person shall not act as a flight crew member or carry out that duty, if the operator or the person has reason to believe that the person is not, or is not likely to be, fit for duty.

Alcohol or Drugs – Crew Members*CAR 602.03*

No person shall act as a crew member of an aircraft

- (a) within 12 hours after consuming an alcoholic beverage;
- (b) while under the influence of alcohol; or
- (c) while using any drug that impairs the person's faculties to the extent that the safety of the aircraft or of persons on board the aircraft is endangered in any way.

Alcohol or Drugs – Passengers*CAR 602.04*

- (1) In this Section, "intoxicating liquor" means a beverage that contains more than 2.5 percent proof spirits.
- (2) No person shall consume on board an aircraft an intoxicating liquor unless the intoxicating liquor
 - (a) has been served to that person by the operator of the aircraft;
 - (b) where no flight attendant is on board, has been provided by the operator of the aircraft.
- (3) No operator of an aircraft shall provide or serve any intoxicating liquor to a person on board the aircraft, where there are reasonable grounds to believe that the person's faculties are

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

impaired by alcohol or a drug to an extent that may present a hazard to the aircraft or to persons on board the aircraft.

- (4) Subject to subsection (5), no operator of an aircraft shall allow a person to board the aircraft, where there are reasonable grounds to believe that the person's faculties are impaired by alcohol or a drug to an extent that may present a hazard to the aircraft or to persons on board the aircraft.
- (5) The operator of an aircraft may allow a person whose faculties are impaired by a drug to board an aircraft, where the drug was administered in accordance with a medical authorization and the person is under the supervision of an attendant.

Compliance with Instructions*CAR 602.05*

- (1) Every passenger on board an aircraft shall comply with instructions given by any crew members respecting the safety of the aircraft or of persons on board the aircraft.
- (2) Every crew member on board an aircraft shall, during flight time, comply with the instructions of the pilot-in-command or of any person whom the pilot-in-command has authorized to act on behalf of the pilot-in-command.

Smoking*CAR 602.06*

- (1) No person shall smoke on board an aircraft during takeoff or landing or when directed not to smoke by the pilot-in-command.
- (2) No person shall smoke in an aircraft lavatory.
- (3) No person shall tamper with or disable a smoke detector installed in an aircraft lavatory without permission from a crew member or the operator of the aircraft.

Aircraft Operating Limitations*CAR 602.07*

No person shall operate an aircraft unless it is operated in accordance with the operating limitations.

- (a) set out in the aircraft flight manual, where an aircraft flight manual is required by the applicable standards of airworthiness;
- (b) set out in a document other than the aircraft flight manual, where use of that document is authorized pursuant to Part VII;
- (c) indicated by markings or placards required pursuant to Section 605.05; or
- (d) prescribed by the competent authority of the state of registry of the aircraft.

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

Portable Electronic Devices*CAR 602.08*

- (1) No operator of an aircraft shall permit the use of a portable electronic device on board an aircraft, where the device may impair the functioning of the aircraft's systems or equipment.
- (2) No person shall use a portable electronic device on board an aircraft except with the permission of the operator of the aircraft.

Carry-on Baggage, Equipment and Cargo*CAR 602.86*

- (1) No person shall operate an aircraft with carry-on baggage, equipment or cargo on board, unless the carry-on baggage, equipment and cargo are
 - (a) stowed in a bin, compartment, rack or other location that is certified in accordance with the aircraft type certificate in respect of the stowage of carry-on baggage, equipment or cargo; or
 - (b) restrained so as to prevent them from shifting during movement of the aircraft on the surface and during takeoff, landing and in-flight turbulence.
- (2) No person shall operate an aircraft with carry-on baggage, equipment or cargo on board unless
 - (a) the safety equipment, the normal and emergency exits that are accessible to passengers and the aisles between the flight deck and a passenger compartment are not wholly or partially blocked by carry-on baggage, equipment or cargo;
 - (b) all of the equipment and cargo that are stowed in a passenger compartment are packed or covered to avoid possible injury to persons on board;
 - (c) where the aircraft is type-certified to carry 10 or more passengers and passengers are carried on board,
 - (i) no passenger's view of any "seat belt" sign, "no smoking" sign or exit sign is obscured by carry-on baggage, equipment or cargo except if an auxiliary sign is visible to the passenger or another means of notification of the passenger is available.
 - (ii) all of the passenger service carts and trolleys are securely restrained during movement of the aircraft on the surface, takeoff and landing, and during inflight turbulence where the pilot-in-command or in-charge flight attendant has directed that the cabin be secure pursuant to subsection 605.25(3) or (4), and
 - (iii) all of the video monitors that are suspended from the ceiling of the aircraft and extend into an aisle are stowed and securely restrained during takeoff and landing; and

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

- (d) all of the cargo that is stowed in a compartment to which crew members have access is stowed in such a manner as to allow a crew member to effectively reach all parts of the compartment with a handheld fire extinguisher.

Crew Member Instructions*CAR 602.87*

The pilot-in-command of an aircraft shall ensure that each crew member, before acting as a crew members on board the aircraft, has been instructed with respect to

- (a) the duties that the crew member is to perform; and
- (b) the location and use of all of the normal and emergency exits and of all of the emergency equipment that is carried on board the aircraft.

Passenger Briefings*CAR 602.89*

- (1) The pilot-in-command of an aircraft shall ensure that all of the passengers on board the aircraft are briefed before takeoff with respect to the following, where applicable:
 - (a) the location and means of operation of emergency and normal exits;
 - (b) the location and means of operation of safety belts, should harnesses and restraint devices;
 - (c) the positioning of seats and the securing of seat backs and chair tables;
 - (d) the stowage of carry-on baggage;
 - (e) where the aircraft is unpressurized and it is possible that the flight will require the use of oxygen by the passengers, the location and means of operation of oxygen equipment; and
 - (f) any prohibition against smoking.
- (2) The pilot-in-command of an aircraft shall ensure that all of the passengers on board the aircraft are briefed
 - (a) in the case of an over-water flight where the carriage of life preservers, individual flotation devices or personal flotation devices is required pursuant to Section 602.62, before commencement of the over-water portion of the flight, with respect to the location and use of those items; and
 - (b) in the case of a pressurized aircraft that is to be operated at an altitude above FL250, before the aircraft reaches FL250, with respect to the location and means of operation of oxygen equipment.
- (3) The pilot-in-command of an aircraft shall, before takeoff, ensure that all of the passengers on board the aircraft are provided with information respecting the location and use of
 - (a) first aid kits and survival equipment;

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

- (b) where the aircraft is a helicopter or a small aircraft that is an aeroplane, any ELT that is required to be carried on board pursuant to Section 605.38; and
- any life raft that is required to be carried on board pursuant to Section 602.63.

Noise Operating Criteria*CAR 602.105*

No person shall operate an aircraft at or in the vicinity of an aerodrome except in accordance with the applicable noise abatement procedures and noise control requirements specified by the Minister in the Canada Air Pilot or Canada Flight Supplement, including the procedures and requirements relating to

- (a) preferential runways;
- (b) minimum noise routes;
- (c) hours when aircraft operations are prohibited or restricted;
- (d) arrival procedures;
- (e) departure procedures;
- (f) duration of flights;
- (g) the prohibition or restriction of training flights;
- (h) VFR or visual approaches;
- (i) simulated approach procedures; and
- (j) the minimum altitude for the operation of aircraft in the vicinity of the aerodrome.

Noise-Restricted Runways*CAR 602.106*

- (1) Subject to subsection (2), no person shall operate a subsonic turbojet aeroplane that has a maximum certificated takeoff weight of more than 34,000 kg (74,956 pounds) on takeoff at a noise-restricted runway set out in Column II of an item of the table to this section at an aerodrome set out in Column I of that item, unless there is on board.
- (a) a certificate of airworthiness indicating that the aeroplane meets the applicable noise emission standards;
 - (b) a certificate of noise compliance issued in respect of the aeroplane; or
 - (c) where the aeroplane is not a Canadian aircraft, a document issued by the state of registry that specifies that the aeroplane meets the applicable noise emission requirements of that state.
- (2) Subsection (1) does not apply
- (a) to the extent that it is inconsistent with any obligation assumed by Canada in respect of a foreign state in a treaty, convention or agreement;

CA 15
ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

- (b) where the pilot-in-command of an aircraft has declared an emergency; or
- (c) where an aircraft is operated on
 - (i) an air evacuation operation,
 - (ii) any other emergency air operation, or
 - (iii) a departure from an aerodrome at which it was required to land because of an emergency.

SCHEDULE (Section 602.106)

ITEM	Column I	Column II
	AIRPORT	NOISE RESTRICTED RUNWAYS FOR TAKE-OFF
1	Vancouver International	08L, 08R, 12, 26R
2	Calgary International	07, 10, 16, 25, 28
3	Edmonton City Centre (Blatchford Field)	All runways
4	Edmonton International	12
5	Winnipeg/Richardson International	13, 18
6	Hamilton	06
7	Toronto/Pearson International	05, 06L, 06R, 15L, 15R
8	Ottawa/Macdonald-Cartier International	32
9	Montreal/Trudeau International	All runways

Power-driven Aircraft – Day VFR
CAR 605.14

No person shall conduct a takeoff in a power-driven aircraft for the purpose of day VFR flight unless it is equipped with

- (a) where the aircraft is operated in uncontrolled airspace, an altimeter;
- (b) where the aircraft is operated in controlled airspace, a sensitive altimeter adjustable for barometric pressure;
- (c) an airspeed indicator;
- (d) a magnetic compass or a magnetic direction indicator that operates independently of the aircraft electrical generating system;
- (e) a tachometer for each engine and for each propeller or rotor that has limiting speeds established by the manufacturer;
- (f) an oil pressure indicator for each engine employing an oil pressure system;

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

- (g) a coolant temperature indicator for each liquid-cooled engine;
- (h) an oil temperature indicator for each air-cooled engine having a separate oil system;
- (i) a manifold pressure gauge for each
 - (i) reciprocating engine equipped with a variable-pitch propeller,
 - (ii) reciprocating engine used to power a helicopter,
 - (iii) supercharged engine, and
 - (iv) turbocharged engine;
- (j) a means for the flight crew, when seated at the flight controls to determine
 - (i) the fuel quantity in each main fuel tank, and
 - (ii) if the aircraft employs retractable landing gear, the position of the landing gear;
- (k) subject to subsections 601.08(2) and 601.09(2), a radio-communication system adequate to permit two-way communication on the appropriate frequency when the aircraft is operated within
 - (i) Class “B”, Class “C” or Class “D” airspace,
 - (ii) an MF area, unless the aircraft is operated pursuant to subsection 602.97(3), or
 - (iii) the ADIZ;
- (l) where the aircraft is operated under Subpart 4 of this part, or Subpart 3, 4 or 5 of Part VII, radio-communication equipment adequate to permit two-way communication on the appropriate frequency;
- (m) where the aircraft is operated in Class “B” airspace, radio navigation equipment that will enable it to be operated in accordance with a flight plan; and
- (n) where the aircraft is operated under Subpart 4 of this Part or under Subpart 5 of Part VII, radio navigation equipment that is adequate to receive radio signals from a transmitting facility.

Power-driven Aircraft – VFR OTT*CAR 605.15*

- (1) No person shall conduct a takeoff in a power-driven aircraft for the purpose of VFR OTT flight unless it is equipped with
 - (a) the equipment referred to in paragraphs 605.14(c) to (j);
 - (b) a sensitive altimeter adjustable for barometric pressure;
 - (c) a means of preventing malfunction caused by icing for each airspeed indicating system;
 - (d) a gyroscopic direction indicator or a stabilized magnetic direction indicator;
 - (e) an attitude indicator;

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

- (f) subject to subsection (2), a turn and slip indicator or turn coordinator;
 - (g) where the aircraft is to be operated within the Northern Domestic Airspace, a means of establishing direction that is not dependent on a magnetic source;
 - (h) radiocommunication equipment adequate to permit two-way communication on the appropriate frequency; and
 - (i) radio navigation equipment adequate to permit the aircraft to be navigated safely.
- (2) Where the aircraft is equipped with a standby attitude indicator that is usable through flight attitudes of 360 degrees of pitch and roll for an aeroplane, or +/- 80 degrees of pitch and +/- 120 degrees of roll for a helicopter, the aircraft may be equipped with a slip-skid indicator in lieu of a turn and slip indicator or turn coordinator.

Power-driven Aircraft – Night VFR*CAR 605.16*

- (1) No person shall conduct a takeoff in a power-driven aircraft for the purpose of night VFR flight, unless it is equipped with
- (a) the equipment referred to in paragraphs 605.14(c) to (n);
 - (b) a sensitive altimeter adjustable for barometric pressure;
 - (c) subject to subsection (2), a turn and slip indicator or turn coordinator;
 - (d) an adequate source of electrical energy for all of the electrical and radio equipment;
 - (e) in respect of every set of fuses of a particular rating that is installed on the aircraft and accessible to the pilot-in-command during flight, a number of spare fuses that is equal to at least 50 percent of the total number of installed fuses of that rating;
 - (f) where the aircraft is operated so that an aerodrome is not visible from the aircraft, a stabilized magnetic direction indicator or a gyroscopic direction indicator;
 - (g) where the aircraft is to be operated within the Northern Domestic Airspace, a means of establishing direction that is not dependent on a magnetic source;
 - (h) where the aircraft is an airship operated within controlled airspace, radar reflectors attached in such a manner as to be capable of a 360 degree reflection;
 - (i) a means of illumination for all of the instruments used to operate the aircraft;
 - (j) when carrying passengers, a landing light; and
 - (k) position and anti-collision lights that conform to the Aircraft Equipment and Maintenance Standards.
- (2) Where the aircraft is equipped with a third attitude indicator that is usable through flight attitude of 360° of pitch and roll for an aeroplane, or +/- 80° of pitch and +/- 120° of roll for a helicopter, the aircraft may be equipped with a slip-skid indicator in lieu of a turn and slip indicator or turn coordinator.

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

- (3) No person shall operate an aircraft that is equipped with any light that may be mistaken for, or downgrade the conspicuity of a light in the navigation light system, unless the aircraft is being operated for the purpose of aerial advertising.
- (4) In addition to the equipment requirements specified in subsection (1), no person shall operate an aircraft in night VFR flight under Subpart 4 of this Part or Subparts 2 to 5 of Part VII, unless the aircraft is equipped with
 - (a) an attitude indicator;
 - (b) a vertical speed indicator;
 - (c) a means of preventing malfunction caused by icing for each airspeed indicating system; and
 - (d) an outside air temperature gauge.

Use of Position and Anti-collision Lights*CAR 605.17*

- (1) Subject to subsection (2), no person shall operate an aircraft in the air or on the ground at night, or on water between sunset and sunrise, unless the aircraft position lights and anti-collision lights are turned on.
- (2) Anti-collision lights may be turned off where the pilot-in-command determines that, because of operating conditions, doing so would be in the best interests of aviation safety.

Power-driven Aircraft – IFR*CAR 605.18*

No person shall conduct a takeoff in a power-driven aircraft for the purpose of IFR flight unless it is equipped with

- (a) when it is operated by day, the equipment required pursuant to paragraphs 605.16 (1)(a) to (h);
- (b) when it is operated by night, the equipment required pursuant to paragraphs 605.16 (1)(a) to (k);
- (c) an attitude indicator;
- (d) a vertical speed indicator;
- (e) an outside air temperature gauge;
- (f) a means of preventing malfunction caused by icing for each airspeed indicating system;
- (g) a power failure warning device or vacuum indicator that shows the power available to gyroscopic instruments from each power source;
- (h) an alternative source of static pressure for the altimeter, airspeed indicator and vertical speed indicator;

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

- (i) sufficient radio-communication equipment to permit the pilot to conduct two-way communications on the appropriate frequency; and
- (j) sufficient radio navigation equipment to permit the pilot, in the event of the failure at any stage of the flight of any item of that equipment, including any associated flight instrument display,
 - (i) to proceed to the destination aerodrome or proceed to another aerodrome that is suitable for landing, and
 - (ii) where the aircraft is operated in IMC, to complete an instrument approach and, if necessary, conduct a missed approach procedure.

Balloons – Day VFR*CAR 605.19*

No person shall conduct a takeoff in a balloon for the purpose of day VFR flight unless it is equipped with

- (a) an altimeter;
- (b) a vertical speed indicator;
- (c) in the case of a hot air balloon,
 - (i) a fuel quantity gauge, and
 - (ii) an envelope temperature indicator;
- (d) in the case of a captive gas balloon, a magnetic direction indicator, and
- (e) subject to subsections 601.08(2) and 601.09 (2), a radio-communication system adequate to permit two-way communication on the appropriate frequency when the balloon is operated within
 - (i) Class “C” or Class “D” airspace,
 - (ii) an MF area, unless the aircraft is operated pursuant to subsection 602.97(3), or
 - (iii) the ADIZ.

Balloons – Night VFR*CAR 605.20*

No person shall conduct a takeoff in a balloon for the purpose of night VFR flight unless it is equipped with

- (a) equipment required pursuant to Section 605.19;
- (b) position lights;
- (c) a means of illuminating all of the instruments used by the flight crew, including a flashlight; and
- (d) in the case of a hot air balloon, two independent fuel systems.

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

Gliders – Day VFR*CAR 605.21*

No person shall operate a glider in day VFR flight unless it is equipped with

- (a) an altimeter;
- (b) an airspeed indicator;
- (c) a magnetic compass or a magnetic direction indicator; and
- (d) subject to subsections 601.08(2) and 601.09 (2), a radio-communication system adequate to permit two-way communication on the appropriate frequency when the glider is operated within
 - (i) Class “C” or Class “D” airspace,
 - (ii) an MF area, unless the aircraft is operated pursuant to subsection 602.97(3), or
 - (iii) the ADIZ.

Seat and Safety Belt Requirements*CAR 605.22*

- (1) Subject to subsection 605.23, no person shall operate an aircraft other than a balloon unless it is equipped with a seat and safety belt for each person on board the aircraft other than an infant.
- (2) Subsection (1) does not apply to a person operating an aircraft that was type-certificated with a safety belt designed for two persons.
- (3) A safety belt referred to in subsection (1) shall include a latching device of the metal-to-metal type.

Restrain System Requirements*CAR 605.23*

An aircraft may be operated without being equipped in accordance with Section 605.22 in respect of the following persons if a restraint system that is secured to the primary structure of the aircraft is provided for each person who is

- (a) carried on a stretcher or in an incubator or other similar device;
- (b) carried for the purpose of parachuting from the aircraft; or
- (c) required to work in the vicinity of an opening in the aircraft structure.

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

Shoulder Harness Requirements*CAR 605.24*

- (1) No person shall operate an aeroplane, other than a small aeroplane manufactured before July 18, 1978, unless each front seat or, if the aeroplane has a flight deck, each seat on the flight deck is equipped with a safety belt that includes a shoulder harness.
- (2) Except as provided in Section 705.75, no person shall operate a transport category aeroplane unless each flight attendant seat is equipped with a safety belt that includes a shoulder harness.
- (3) No person shall operate a small aeroplane manufactured after December 12, 1986, the initial type certificate of which provides for not more than nine passenger seats, excluding any pilot seats, unless each forward- or aft-facing seat is equipped with a safety belt that includes a shoulder harness.
- (4) No person shall operate a helicopter manufactured after September 16, 1992, the initial type certificate of which specifies that the helicopter is certified as belonging to the normal or transport category, unless each seat is equipped with a safety belt that includes a shoulder harness.
- (5) No person operating an aircraft shall conduct any of the following flight operations unless the aircraft is equipped with a seat and safety belt that includes a shoulder harness for each person on board the aircraft:
 - (a) aerobatic manoeuvres;
 - (b) Class "B," "C" or "D" external load operations conducted by a helicopter; and
 - (c) aerial application, or aerial inspection other than flight inspection for the purpose of calibrating electronic navigation aids, conducted at altitudes below 500" AGL.

General Use of Safety Belts and Restraint Systems*CAR 605.25*

- (1) The pilot-in-command of an aircraft shall direct all of the persons on board the aircraft to fasten safety belts.
 - (a) during movement of the aircraft on the surface;
 - (b) during takeoff and landing; and
 - (c) at any time during flight that the pilot-in-command considers it necessary that safety belts be fastened.
- (2) The directions referred to in subsection (1) also apply to the use of the following restraint systems:
 - (a) a child restraint system;
 - (b) a restraint system used by a person who is engaged in parachute descents; and

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

- (c) a restraint system used by a person when working in the vicinity of an opening in the aircraft structure.
- (3) Where an aircraft crew includes flight attendants and the pilot-in-command anticipates that the level of turbulence will exceed light turbulence, the pilot-in-command shall immediately direct each flight attendant to
 - (a) discontinue duties relating to service;
 - (b) secure the cabin; and
 - (c) occupy a seat and fasten the safety belt provided.
- (4) Where an aircraft is experiencing turbulence and the in-charge flight attendant considers it necessary, the in-charge flight attendant shall
 - (a) direct all of the passengers to fasten their safety belts; and
 - (b) direct all flight attendants to discontinue duties relating to service, to secure the cabin, to occupy the assigned seats and to fasten the safety belts provided and to do so one-self.
- (5) Where the in-charge flight attendant has given directions in accordance with subsection (4), the in-charge flight attendant shall so inform the pilot-in-command.

Use of Passenger Safety Belts and Restraint Systems*CAR 605.26*

- (1) Where the pilot-in-command or the in-charge flight attendant directs that safety belts be fastened, every passenger who is not an infant shall
 - (a) ensure that the passenger's safety belt or restraint system is properly adjusted and securely fastened;
 - (b) if responsible for an infant for which no child restraint system is provided, hold the infant securely in the passenger's arms; and
 - (c) if responsible for a person who is using a child restraint system, ensure that the person is properly secured.
- (2) No passenger shall be responsible for more than one infant.

Use of Crew Member Safety Belts*CAR 605.27*

- (1) Subject to subsection (2), the crew members on an aircraft shall be seated at their stations with their safety belts fastened
 - (a) during takeoff and landing;
 - (b) at any time that the pilot-in-command directs; and

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

- (c) in the case of crew members who are flight attendants, at any time that the in-charge flight attendant so directs pursuant to paragraph 605.25(4)(b).
- (2) Where the pilot-in-command directs that safety belts be fastened by illuminating the safety belt sign, a crew member is not required to comply with paragraph (1)(b)
- (a) during movement of the aircraft on the surface or during flight, if the crew member is performing duties relating to the safety of the aircraft or of the passengers on board;
 - (b) where the aircraft is experiencing light turbulence, if the crew member is a flight attendant and is performing duties relating to the passengers on board; or
 - (c) if the crew member is occupying a crew rest facility during cruise flight and the restraint system for that facility is properly adjusted and securely fastened.
- (3) The pilot-in-command shall ensure that at least one pilot is seated at the flight controls with safety belt fastened during flight time.

Child Restraint System*CAR 605.28*

- (1) No operator of an aircraft shall permit the use of a child restraint system on board the aircraft unless
- (a) the person using the child restraint system is accompanied by a parent or guardian who will attend to the safety of the person during the flight;
 - (b) the weight and height of the person using the child restraint system are within the range specified by the manufacturer;
 - (c) the child restraint system bears a legible label indicating the applicable design standards and date of manufacture;
 - (d) the child restraint system is properly secured by the safety belt of a forward-facing seat that is not located in an emergency exit row and does not block access to an aisle; and
 - (e) the tether strap is used according to the manufacturer's instructions or, where subsection (2) applies, secured so as not to pose a hazard to the person using the child restraint system or to any other person.
- (2) Where a seat incorporates design features to reduce occupant loads, such as the crushing or separation of certain components, and the seat is in compliance with the applicable design standards, no person shall use the tether strap on the child restraint system to secure the system.
- (3) Every passenger who is responsible for a person who is using a child restraint system on board an aircraft shall be
- (a) seated in a seat adjacent to the seat to which the child restraint system is secured;
 - (b) familiar with the manufacturer's installation instructions for the child restraint system; and

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

- (c) familiar with the method of securing the person in the child restraint system and of releasing the person from it.

Flight Control Locks*CAR 605.29*

No operator of an aircraft shall permit the use of a flight control lock in respect of the aircraft unless

- (a) the flight control lock is incapable of becoming engaged when the aircraft is being operated; and
- (b) an unmistakable warning is provided to the person operating the aircraft whenever the flight control lock is engaged.

De-icing or Anti-icing Equipment*CAR 605.30*

No person shall conduct a takeoff or continue a flight in an aircraft where icing conditions are reported to exist or are forecast to be encountered along the route of flight unless

- (a) the pilot-in-command determines that the aircraft is adequately equipped to operate in icing conditions in accordance with the standards of airworthiness under which the type certificate for that aircraft was issued; or
- (b) current weather reports or pilot reports indicate that icing conditions no longer exist.

Oxygen Equipment and Supply*CAR 605.31*

- (1) No person shall operate an unpressurized aircraft unless it is equipped with sufficient oxygen dispensing units and oxygen supply to comply with the requirements set out in the table to this subsection.

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

OXYGEN REQUIREMENTS FOR UNPRESSURIZED AIRCRAFT

Item	Column I Persons For Whom Oxygen Supply Must be Available	Column II Period Of Flight and Cabin-Pressure- Altitude
1.	All crew members and 10 percent of passengers and, in any case, no less than one passenger.	Entire period of flight exceeding 30 minutes at cabin-pressure-altitudes above 10,000 feet ASL but not exceeding 13,000 feet ASL.
2.	All persons on board the aircraft.	(a) Entire period of flight at cabin-pressure-altitudes above 13,000 feet ASL. (b) For aircraft operated in an air transport service under the conditions referred to in paragraph (a), a period of flight of not less than one hour.

- (2) No person shall operate a pressurized aircraft unless it is equipped with sufficient oxygen dispensing units and oxygen supply to provide, in the event of cabin pressurization failure at the most critical point during the flight, sufficient oxygen to continue the flight to an aerodrome suitable for landing while complying with the requirements of the table to this subsection.

CA 15
ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)
MINIMUM OXYGEN REQUIREMENTS FOR PRESSURIZED AIRCRAFT FOLLOWING EMERGENCY DESCENT (NOTE 1)

Item	Column I Persons For Whom Oxygen Supply Must be Available	Column II Period Of Flight and Cabin-Pressure-Altitude
1.	All crew members and 10 percent of passengers and, in any case, no less than one passenger	(a) Entire period of flight exceeding 30 minutes at cabin-pressure-altitudes above 10,000 feet ASL but not exceeding 13,000 feet ASL (b) Entire period of flight at cabin-pressure-altitudes above 13,000 feet ASL (c) For aircraft operated in an air transport service under the conditions referred to in paragraph (a) or (b), a period of flight of not less than (i) 30 minutes (Note 2), and (ii) for flight crew members, two hours for aircraft the type certificate of which authorizes flight at altitudes exceeding FL250 (Note 3)
2.	All passengers.	(a) Entire period of flight at cabin-pressure-altitudes exceeding 13,000 feet ASL. (b) For aircraft operated in an air transport service under the conditions referred to in paragraph (a), a period of flight of not less than 10 minutes

NOTE:

1. In determining the available supply, the cabin pressure altitude descent profile for the routes concerned must be taken into account.
2. The minimum supply is that quantity of oxygen necessary for a constant rate of descent from the aircraft's maximum operating altitude authorized in the type certificate to 10,000 feet ASL in 10 minutes, followed by 20 minutes at 10,000 feet ASL.
3. The minimum supply is that quantity of oxygen necessary for a constant rate of descent from the aircraft's maximum operating altitude authorized in the type certificate to 10,000 feet ASL in 10 minutes, followed by 110 minutes at 10,000 feet ASL.

CA 15

ATC ANNEX - CANADIAN AVIATION REGULATIONS (CARS)

Use of Oxygen*CAR 605.32*

- (1) Where an aircraft is operated at cabin-pressure-altitudes above 10,000 feet ASL but not exceeding 13,000 feet ASL, each crew member shall wear an oxygen mask and use supplemental oxygen for any part of the flight at those altitudes that is more than 30 minutes in duration.
- (2) Where an aircraft is operated at cabin-pressure-altitudes above 13,000 feet ASL, each person on board the aircraft shall wear an oxygen mask and use supplemental oxygen for the duration of the flight at those altitudes.
- (3) The pilot at the flight controls of an aircraft shall use an oxygen mask if
 - (a) the aircraft is not equipped with quick-donning oxygen masks and is operated at or above FL250; or
 - (b) the aircraft is equipped with quick-donning oxygen masks and is operated above FL410.

CANADA
RULES AND PROCEDURES

GENERAL

The air traffic rules and procedures applicable to air traffic in Canadian territory conform to Annex 2, “Rules of the Air,” and Annex 11, “Air Traffic Services,” to the Convention on International Civil Aviation and to those portions of the International Civil Aviation Organization's (ICAO) Procedures for Air Navigation Services—*Air Traffic Management* (PANS–ATM, Doc 4444) and *Air Traffic Services Planning Manual* (Doc 9426) that are applicable to aircraft and to those portions of ICAO's *Regional Supplementary Procedures* (Doc 7030) that are applicable to the Canadian region, except for the differences listed in “Differences from ICAO Standards and Procedures.”

The Imperial system of units is used for all information contained on aeronautical charts and publications. Other units are given in the following table and apply to specific situations.

Measurement	Units
Altimeter setting	inches of mercury
Altitudes, elevations and heights	feet
Distance used in navigation	nautical miles
Horizontal speed	knots
Relatively short distances	feet
Runway Visual Range (RVR)	feet
Temperature	degrees Celsius
Tire Pressure	pounds per square inch megapascals
Vertical speed	feet per minute
Visibility	statute miles
Weight	pounds/kilograms/ kilonewtons
Wind direction, except for landing and takeoff	degrees true
Wind direction in observations for landing and takeoff (degrees true in the Northern Domestic Airspace)	degrees magnetic
Wind speed	knots

WGS-84 COMPLIANT

FLIGHT PROCEDURES

HOLDING

Maximum Speeds

The size of the protected airspace for a holding pattern is based on aircraft speed. Unless otherwise noted on the charts or when a shuttle procedure is specified holding patterns must be entered and flown at or below the airspeeds listed below:

CANADA RULES AND PROCEDURES

Maximum Holding Airspeeds

Altitude (ASL)	Maximum Holding Airspeed (KIAS)
At or below 6000 ft	200
Above 6000 ft up to and including 14,000 ft	230
Above 14,000 ft	265

NOTE 1: At Canadian military airfields, the size of the protected airspace is for a maximum of 310 KIAS, unless otherwise noted.

NOTE 2: For helicopter procedures (COPTER), the maximum holding airspeed is 90 KIAS, unless otherwise noted.

Pilots are to advise ATC immediately if airspeeds in excess of those specified above become necessary for any reason, including turbulence, or if unable to accomplish any part of the holding procedure.

After departing a holding fix, pilots should resume normal speed subject to other requirements, such as speed limitations in the vicinity of controlled airports, specific ATC requests, etc.

NOTE: In areas where turbulence is known to exist, holding patterns may be designed for speeds of 280 KIAS.

PROCEDURE LIMITATIONS AND OPTIONS

Canada does not use ICAO's *Procedures for Air Navigation Services—Aircraft Operations* (PANS OPS). Instead, Canada uses the *Criteria for the Development of Instrument Procedures* (TP 308), which is a document developed and produced by Transport Canada, Airports and Air Navigation Branch.

AIRCRAFT APPROACH CATEGORIES

Aircraft performance has a direct effect on the airspace and visibility required for the various maneuvers associated with the conduct of an instrument approach procedure. The most significant performance factor is aircraft speed. For this reason, a number of aircraft approach categories, each with a specified speed range, have been established.

An aircraft's approach category is determined based on its reference landing speed (V_{ref}), if specified, or if V_{ref} is not specified, 1.3 times stall speed (V_{so}) at the maximum certificated landing weight. V_{ref} , V_{so} , and the maximum certificated landing weight are those values as established for the aircraft by the certification authority of the country of registry. The categories are as follows:

Aircraft Approach Categories

CATEGORY	A	B	C	D	E
SPEEDS	up to 90 KIAS (includes all rotorcraft)	91 to 120 KIAS	121 to 140 KIAS	141 to 165 KIAS	above 165 KIAS

CANADA RULES AND PROCEDURES

NOTE: Category E minima are not provided for on civil instrument approach procedure charts.

An aircraft's approach category does not change if the actual landing weight is less than the maximum certificated landing weight. The certificated approach category is permanent and independent of the changing conditions of day-to-day operations. An aircraft is certificated in only one approach category and cannot be flown to the minima of a slower approach category. For example, a Category C aircraft cannot utilize Category B minima.

However, if the requirement for a faster approach speed places the aircraft in a higher speed approach category, the minima for the appropriate higher category must be used. This may be due to operational circumstances such as emergency returns requiring overweight landing or approaches made with inoperative flaps or in icing conditions. Additionally, if it is necessary to visually maneuver at speeds in excess of the upper limit of a speed range for a category, the minima for the category for that higher speed must be used. For example, an aircraft which falls in Category A, but is circling to land at a speed in excess of 90 kt, must use the approach Category B minima when circling to land.

Aircraft Speed Limit Order

According to CAR 602.32, no person shall operate an aircraft in Canada

- a. below 10,000 ft ASL at more than 250 KIAS; or
- b. below 3000 ft AGL within 10 NM of a controlled airport and at more than 200 KIAS, unless authorized to do so in an air traffic control clearance.

Exceptions:

- a. A person may operate an aircraft at an indicated airspeed greater than the airspeeds referred to in a. and b. above where the aircraft is being operated in accordance with a special flight operations certificate – special aviation event issued under CAR 603.
- b. If the minimum safe speed, given the aircraft configuration, is greater than the speed referred to in a. or b. above, the aircraft shall be operated at the minimum safe speed.

Notifying ATC

On departure, when intending to operate at speeds exceeding 250 KIAS below 10,000 ft ASL, pilots must, on initial contact, notify the departure controller of the reason for this action.

ATC requires this information for the following reasons:

- for operational considerations regarding other traffic, particularly in potential overtake situations; and
- so that ATC will know that the request or notification of intent to operate above the speed limit is for “*minimum safe speed*” requirements and will therefore not file an Aviation Occurrence Report.

The phraseology of “*minimum safe speed XXX kt*” is encouraged and ATC will acknowledge.

EXAMPLE: *Montreal Centre, ACA123, minimum safe speed 270 kt*

CANADA RULES AND PROCEDURES

As ATC is not authorized to approve a speed greater than 250 KIAS below 10,000 ft ASL, the phraseology “request high-speed climb” should not be used.

Circling Approach Area

The visual manoeuvring area for a circling approach is determined by drawing arcs centred on each runway threshold and joining those arcs with tangent lines. The radius of the arcs is related to the aircraft category and may be based on either standard circling approach radii or expanded circling approach radii (see sections below). The circling minimum descent altitude (MDA) provides a minimum of 300 feet above all obstacles within the visual manoeuvring area for each category.

Standard Circling Approach Radii

Circling approach protected areas developed prior to 2020 used the radius distances shown in the following table. Approaches using standard circling approach areas can be identified by the **absence** of the  symbol on the circling line of minima.

Standard Circling Approach Radii

Circling MDA in feet AMSL	Approach Category and Circling Radius (NM)				
	CAT A	CAT B	CAT C	CAT D	CAT E*
All altitudes	1.3	1.5	1.7	2.3	4.5
*Category E circling minima are published at DND airports only.					

Expanded Circling Approach Radii

Circling approach protected areas developed in 2020 or later use a radius distance based on the aircraft category as well as the altitude of the circling MDA, which accounts for increases to true airspeed with altitude. The following table provides radius values for each aircraft category within five altitude bands. Approaches using expanded circling approach areas can be identified by the **presence** of the  symbol on the circling line of minima.

Expanded Circling Approach Radii

Circling MDA in feet AMSL	Approach Category and Circling Radius (NM)				
	CAT A	CAT B	CAT C	CAT D	CAT E*
1000 or less	1.3	1.7	2.7	3.6	4.5
1001 – 3000	1.3	1.8	2.8	3.7	4.6
3001 – 5000	1.3	1.8	2.9	3.8	4.8
5001 – 7000	1.3	1.9	3.0	4.0	5.0

CANADA RULES AND PROCEDURES

Expanded Circling Approach Radii (continued)

Circling MDA in feet AMSL	Approach Category and Circling Radius (NM)				
7001 – 9000	1.4	2.0	3.2	4.2	5.3
*Category E circling minima are published at DND airports only.					

Advance Notice of Intent in Minimum Weather Conditions

ATC can handle missed approaches more efficiently if the controller knows the pilot's intentions in advance. They can use the extra time to plan for the possibility of a missed approach and thus provide better service in the event of an actual missed approach.

Pilots should adopt the following procedures as the occasion arises.

On receipt of approach clearance, when the ceiling and visibility reported at the destination airport is such that a missed approach is probable, the pilot should advise the controller as follows:

IN THE EVENT OF MISSED APPROACH REQUEST (altitude or level) VIA (route) TO (airport).

Implementation of this procedure increases the amount of communications, but the increase can be minimized if pilots employ it only when there is a reasonable chance that a missed approach may occur.

Contact Approach

A contact approach is an approach wherein an aircraft on an IFR flight plan or flight itinerary, having an ATC clearance, operating clear of clouds with at least 1 NM flight visibility and a reasonable expectation of continuing to the destination airport in those conditions, may deviate from the instrument approach procedure and proceed to the destination airport by visual reference to the surface of the earth. In accordance with CAR 602.124, the aircraft shall be flown at an altitude of at least 1000 feet above the highest obstacle located within a horizontal radius of 5 NM from the estimated position of the aircraft in flight until the required visual reference is acquired in order to conduct a normal landing. Pilots are cautioned that conducting a contact approach in minimum visibility conditions introduces hazards to flight not experienced when flying IFR procedures. Familiarity with the airport environment, including local area obstacles, terrain, noise sensitive areas, Class F airspace and airport layout, is paramount for a successful contact approach in minimum visibility conditions. Pilots are responsible for the adherence to published noise abatement procedures and compliance with any restrictions that may apply to Class F airspace when conducting a contact approach.

NOTE: *This type of approach will only be authorized by ATC when:*

- a. the pilot requests it; and*
- b. there is an approved functioning instrument approach or a published GNSS approach for the airport.*

CANADA RULES AND PROCEDURES

An aircraft that requests a contact approach to an airport served only by a GNSS approach is indicating to ATS that the pilot understands that no ground-based approach is available and is confirming that it is able to conduct a GNSS approach.

ATC will ensure IFR separation from other IFR flights and will issue specific missed approach instructions if there is any doubt that a landing will be accomplished. Pilots are cautioned that when any missed approach is initiated while conducting a contact approach, obstacle and terrain avoidance is the pilot's responsibility even though specific missed approach instructions may have been issued by ATC. ATC only ensures appropriate IFR separation from other IFR aircraft during contact approaches.

NOTE: ATC will not issue an IFR approach clearance that includes clearance for a contact approach unless there is a published and functioning IAP or a restricted instrument approach procedure (RIAP) authorized by TC for the airport. Where a GNSS approach is the only available IAP or RIAP, this fulfills the requirement for a "functioning instrument approach."

AIRPORT OPERATING MINIMUMS

CAR 602 specifies that takeoff is governed by visibility only, approach restrictions are governed by RVR values only and, landings by published DH/MDAs only.

Take-off Minima

CAR 701.20—Take-off Minima states that:

For the purposes of section 602.126, a person may conduct a take-off in an aircraft where weather conditions are below the take-off minima specified in the *Canada Air Pilot* if:

- in the case of a foreign air operator, the foreign air operator is authorized to do so in its Canadian foreign air operator certificate and complies with the *Commercial Air Service Standards*; or
- in the case of a person who operates a foreign state aircraft, the person is authorized to do so in a flight authorization and complies with the *Commercial Air Service Standards*.

Subsection (1) of CAR 602.126—Take-off Minima states that:

No pilot-in-command of an aircraft shall conduct a take-off if the take-off visibility, as determined in accordance with subsection (2), is below the minimum take-off visibility specified in:

- the air operator certificate where the aircraft is operated in accordance with Part VII;
- a special authorization issued under subsection 604.05(2); or
- the *Canada Air Pilot* in any case other than a case described in paragraph a. or b.

Subsection (2) of CAR 602.126 states that:

For the purposes of subsection (1), the take-off visibility is:

- the RVR of the runway, if the RVR is reported to be at or above the minimum take-off visibility specified in a document or the manual referred to in subsection (1);
- the ground visibility of the airport for the runway, if the RVR

CANADA RULES AND PROCEDURES

1. is reported to be less than the minimum take-off visibility specified in a document or the manual referred to in subsection (1),
 2. is reported to vary between distances less than and greater than the minimum take-off visibility specified in the *Canada Air Pilot* or a certificate referred to in subsection (1), or
 3. is not reported; or
- c. the runway visibility as observed by the pilot-in-command, if
1. the RVR is not reported, and
 2. the ground visibility of the airport is not reported.

With respect to takeoff visibility, pilots will be advised of the ground visibility by the appropriate ATS unit.

In summary, a takeoff is authorized when:

- a. the lowest reported RVR for the runway is at or above the minimum takeoff visibility, regardless of reported ground visibility;
- b. the reported ground visibility for the airport is at or above the minimum takeoff visibility, regardless of the reported RVR for the runway; or
- c. in the absence of a reported RVR or reported ground visibility, the runway visibility as observed by the pilot-in-command is at or above minimum takeoff visibility.

Landing Minima

CAR 602.128 specifies that landings are governed by published DH/MDAs. Pilots of aircraft on instrument approaches are prohibited from continuing the final approach descent below DH or descending below MDA, as applicable, unless the required visual reference has been established and maintained in order to complete a safe landing. When the required visual reference is not established and maintained, a missed approach must be initiated. Pilots must be cautioned that the missed approach segment that provides for obstacle clearance originates at the published missed approach point (MAP). The published MAP on a precision approach is coincidental with the DH. Missed approaches initiated beyond the MAP will not be assured obstacle clearance.

Published landing visibilities associated with all instrument approach procedures are *advisory only*. Their values are indicative of visibilities which, if prevailing at the time of approach, should result in required visual reference being established. They are not limiting and are intended to be used by pilots only to judge the probability of a successful landing when compared against available visibility reports at the airport to which an instrument approach is being carried out.

REQUIREMENTS FOR ALTERNATE AIRPORT — IFR FLIGHTS

Except as otherwise authorized by the Minister in an air operator certificate or in a private operator certificate, no pilot-in-command shall operate an aircraft in IFR flight unless the IFR flight plan or IFR flight itinerary that has been filed for the flight includes an alternate airport having a landing area suitable for use by that aircraft. No pilot-in-command of an aircraft shall include an alternate airport in an IFR flight plan or IFR flight itinerary unless available weather information indicates that the ceiling and ground visibility at the alternate airport will, at the expected time of arrival, be

CANADA
RULES AND PROCEDURES

at or above the alternate airport weather minima criteria specified on the Jeppesen Airport chart. (CAR 602.122 and 602.123)

Area Navigation (RNAV) Approaches at Alternate Airports

Pilots may take credit for an area navigation (RNAV) approach at an alternate airport as outlined in ATC — FLIGHT PLANNING, Alternate Airport Weather Minima Requirements.

Taking credit for RNAV approaches at an alternate airport for instrument flight rules (IFR) flight plan filing purposes is possible because the availability of receiver autonomous integrity monitoring (RAIM) or wide area augmentation system (WAAS) integrity is normally very high. However, when satellites are out of service, availability could decrease. Consequently, it is necessary to determine satellite status to ensure that the necessary level of integrity will be available.

Approach Ban

General Aviation–Non-Precision Approach (NPA), Approach Procedure with Vertical Guidance (APV), CAT I or CAT II Precision Approach

CAR 602.129 specifies that instrument approaches by general aviation aircraft are governed by RVR values only. With certain exceptions, pilots of aircraft are prohibited from completing an instrument approach past the FAF (or where there is no FAF, the point where the final approach course is intercepted) to a runway served by an RVR if the RVR values measured for that runway are below the following minima:

MINIMUM RVR

MEASURED RVR	AIRCRAFT
RVR “A” ONLY	1200
RVR “A” AND “B”	1200 / 600
RVR “B” ONLY	1200
RVR “A” located adjacent to the runway threshold.	
RVR “B” located adjacent to the runway mid-point.	

The following exceptions to the above prohibitions apply to all aircraft when:

- a. the below-minima RVR report is received, the aircraft is inbound on approach and has passed the FAF, or where there is no FAF, the point where the final approach course is intercepted;
- b. the pilot-in-command has informed the appropriate ATC unit that the aircraft is on a training flight and that the pilot-in-command intends to initiate a missed approach procedure at or above the DH or the MDA, as appropriate;
- c. the RVR is varying between distances less than and greater than the minimum RVR;
- d. the RVR is less than the minimum RVR, and the ground visibility at the airport where the runway is located is reported to be at least one-quarter statute mile; or

CANADA
RULES AND PROCEDURES

- e. the pilot-in-command is conducting a precision approach to CAT III minima.

With respect to approach restrictions, in the case of a localized phenomenon or any fluctuations that affect RVR validity, where the ground visibility is reported by ATC or FSS to be at or above one-quarter statute mile, an approach may be completed.

If, after commencing an approach (but before reaching the FAF, or where there is no FAF, the point where the final approach course is intercepted), a pilot must discontinue an approach because the RVR has gone below minima, the pilot shall continue as cleared, advise ATC of their intentions and request further clearance. If further clearance is not received by the time the aircraft reaches the FAF, or where there is no FAF, the point where the final approach course is intercepted, the pilot shall execute a missed approach and proceed via the missed approach procedure to the specified missed approach clearance limit.

In summary, an approach is authorized whenever:

- a. the lowest reported RVR for the runway is at or above minima (CAR 602.129), regardless of reported ground visibility;
- b. the RVR is reported to be varying between distances less than and greater than the minimum RVR;
- c. the RVR is below the minimum, and the ground visibility is reported to be at least one-quarter statute mile;
- d. the RVR for the runway is unavailable or not reported; or
- e. ATS is informed that an aircraft is on a training flight and will conduct a planned missed approach.

No pilot shall commence an NPA, an APV, or a CAT I or CAT II precision approach to an airport where low-visibility procedures are in effect. Low-visibility procedures are associated with CAT III operations. They are specified for an airport (for example, CYVR or CYYZ) and restrict aircraft and vehicle operations on the movement area of the airport when the RVR is less than 1,200 ft.

General Aviation—CAT III Precision Approach

CAR 602.130 specifies the general aviation CAT III precision approach ban. No pilot shall continue a CAT III precision approach in an IFR aircraft beyond the FAF inbound, or where there is no FAF, the point where the final approach course is intercepted, unless the RVR reported is equal to or greater than the minimum RVR specified on the approach chart in respect of the runway or surface of intended approach for the IAP conducted.

**CANADA
RULES AND PROCEDURES****MINIMUM RVR—AIRCRAFT—CAT III**

MEASURED RVR	CAT IIIA	CAT IIIB	CAT IIIC
RVR “A”, “B” and “C”	600/600/600	Not Authorized	Not Authorized
RVR “A” located adjacent to the runway threshold.			
RVR “B” located adjacent to the runway mid-point.			
RVR “C” located adjacent to the runway end.			

Aircraft Radio Control of Airport Lighting (ARCAL)

Aircraft radio control of airport lighting (ARCAL) systems are becoming more prevalent as a means of conserving energy, especially at airports not staffed on a continuous basis or where it is not practicable to install a land line to a nearby flight service station (FSS). Aside from obstacle lights, some or all of the airport lighting may be radio-controlled.

Control of the lights should be possible when aircraft are within 15 NM of the airport. The frequency range is 118 to 136 MHz.

The system is activated via the aircraft very high frequency (VHF) transmitter and by pressing the push-to-talk button on the microphone a given number of times within a specified number of seconds. Each activation will start a timer to illuminate the lights for a period of approximately 15 min. The timing cycle may be restarted at any time by repeating the specified keying sequence. It should be noted that for ARCAL Type K runway threshold identification lights (RTIL) (code AS) can be turned off by keying the microphone three times on the appropriate frequency. The code for the intensity and the lighting period varies for each installation. Consequently, the AIRPORT DIRECTORY — CANADA must be consulted for each installation.

NOTE: Pilots are advised to key the activating sequence when beginning their approach, even if the airport lighting is on. This will restart the timing so that the full 15-min cycle is available for their approach.

NOISE ABATEMENT

Nothing in these procedures shall prevent the pilot-in-command from exercising his/her authority for the safe operation of the airplane, except that when a climb gradient is published, it must be maintained, or alternate procedures must be adopted.

The procedures herein describe the methods for noise abatement when a noise problem is evident. They can comprise any one or more of the following:

- use of noise preferential runways to direct the initial and final flight paths of airplanes away from noise-sensitive areas;
- use of noise preferential routes to assist airplanes in avoiding noise-sensitive areas on departure and arrival, including the use of turns to direct airplanes away from noise-sensitive areas located under or adjacent to the usual takeoff and approach flight paths; and

CANADA RULES AND PROCEDURES

- c. use of noise abatement takeoff or approach procedures, designed to minimize the overall exposure to noise on the ground and, at the same time, maintain the required levels of flight safety.

Noise Preferential Runways

Preferred runway directions for takeoff are designated for noise abatement purposes; the objective being to use, whenever possible, those runways that permit aeroplanes to avoid noise-sensitive areas during the initial departure and final approach phases of flight.

Noise abatement is not the determining factor in runway designation under the following circumstances:

- a. if the runway is not clear and dry, i.e., it is adversely affected by snow, slush, ice, water, mud, rubber, oil or other substances;
- b. when the crosswind component, including gusts, exceeds 25 KIAS; and
- c. when the tail wind component, including gusts, exceeds 5 kt.

NOTE: Although ATS personnel may select a preferential runway in accordance with the foregoing criteria, pilots are not obligated to accept the runway for taking off or landing. It remains the pilot's responsibility to decide if the assigned runway is operationally acceptable.

Noise Abatement Departure Procedures (NADP)

NADPs are designed to minimize the environmental impact of departing aircraft without compromising safety. Typically, operators require two procedures: one to minimize close-in noise (NADP 1), the other to minimize noise over a more distant noise-sensitive area (NADP 2).

Under the NADP concept, airport operators identify their noise and emission control needs and may identify specific noise-sensitive areas. Aircraft operators choose the departure method that safely meets the airport operator's objectives.

NADP 1 (Criteria for a Close-in Noise-sensitive Area) Description

This procedure involves a power reduction at or above the prescribed minimum altitude (no less than 800 ft) AAE and delaying flap/slat retraction until the prescribed maximum altitude (3000 ft) AAE is attained. At 3000 ft AAE, accelerate and retract flaps/slats on schedule, while maintaining a positive rate of climb, and complete the transition to normal enroute climb speed. The initial climbing speed to the noise abatement initiation point is no less than $V_2 + 10$ kt.

In summary:

- a. Initial climb to at least 800 ft AAE:
 1. power/thrust as set for take-off;
 2. flaps/slats in take-off configuration; and
 3. climb speed not less than $V_2 + 10$ kt.
- b. At or above 800 ft AAE:
 1. initiate power/thrust reduction;

CANADA RULES AND PROCEDURES

2. maintain climb speed not less than $V_2 + 10$ kt to 20 kt; and
 3. maintain flaps/slats in take-off configuration.
- c. At 3000 ft AAE:
1. maintain positive rate of climb;
 2. accelerate to enroute climb speed; and
 3. retract flaps/slats on schedule.

NOTE: To assist in planning departure spacing, pilots intending to use NADP 1 at Canadian airports are to notify ATC Clearance Delivery or Ground Control. At airports where NADP 1 is the only procedure to follow, ATC does not need to be notified.

NADP 2 (Criteria for a More Distant Noise-sensitive Area) Description

This procedure involves the initiation of flap/slat retraction and accelerating towards V_{ZF} at or above the prescribed minimum altitude (800 ft) AAE but before reaching the prescribed maximum altitude (3000 ft) AAE. The flaps/slats are to be retracted on schedule, while maintaining a positive rate of climb. Intermediate flap retraction, if required for performance, may be accomplished below the prescribed minimum altitude. The power/thrust reduction is initiated at a point along the acceleration segment that ensures satisfactory acceleration performance. At the prescribed maximum altitude, complete the transition to normal enroute climb procedures. The initial climbing speed to the noise abatement initiation point is no less than $V_2 + 10$ kt and the noise abatement procedure is not to be initiated at less than 800 ft AAE.

In summary:

- a. Initial climb to at least 800 ft AAE:
 1. power/thrust as set for take-off;
 2. flaps/slats in take-off configuration; and
 3. climb speed not less than $V_2 + 10$ kt.
- b. At or above 800 ft AAE, maintain a positive rate of climb and accelerate towards V_{ZF} :
 1. retract flaps/slats on schedule; and
 2. reduce power/thrust at a point along the acceleration segment that ensures satisfactory acceleration performance.
- c. Continue the climb to 3000 ft AAE at a climb speed of not less than V_{ZF} ; and
- d. At 3000 ft AAE, transition to normal enroute climb speed.

STANDARD INSTRUMENT DEPARTURE (SID)

At certain airports, an instrument flight rules (IFR) departure clearance may include departure instructions known as a standard instrument departure (SID). A SID is a planned IFR air traffic control (ATC) departure procedure, for pilot and controller use in graphic and textual form. SIDs provide a transition from the terminal to the appropriate enroute structure, and may be either:

CANADA
RULES AND PROCEDURES

- a. **pilot navigation SIDs** — established where the pilot is required to use the chart as reference for navigation to the enroute phase; or
- b. **vector SIDs** — established where ATC will provide radar navigational guidance to a filed/assigned route or to a fix depicted on the chart. Pilots are expected to use the SID chart as reference for navigation until radar vectoring has commenced.

SIDs incorporate obstacle and terrain clearance within the procedure. Pilots should note, however, that SIDs for military airports that are only available in textual form do not incorporate obstacle and terrain clearance. At these airports, it is the pilot's responsibility to ensure appropriate obstacle and terrain clearance on departure.

Pilots of aircraft operating at airports for which SIDs have been published will normally be issued a SID clearance by ATC. No pilot is required to accept a SID clearance. If any doubt exists as to the meaning of such a clearance, the pilot should request a detailed clearance.

Routings contained in SIDs will normally be composed of two segments:

- a. an initial segment from the departure end of the runway to the position where the aircraft will first turn from the initial departure heading; and
- b. a second segment, either via radar vectors or by pilot navigation, from the first turning point to the SID termination point.

When instructed to fly runway heading or when flying a SID for which no specific heading is published, pilots are expected to fly or maintain the heading that corresponds with the extended center line of the departure runway until otherwise instructed by ATC. Drift correction must not be applied; e.g. Runway 04, if the actual magnetic heading of the runway center line is 044 degrees, then fly a heading of 044 degrees M.

When flying a SID for which a specific heading is published, the pilot is expected to steer the published SID heading until radar vectoring commences. This is because initial separation is based on divergence between assigned headings until radar separation is established.

If an aircraft is issued a vector SID, radar vectors will be used, as traffic permits, to provide navigational guidance to the filed/assigned route and over the SID termination fix. However, if the controller or the aircraft will gain an operational advantage, the aircraft may be vectored on a route that will not take the aircraft over the SID termination fix.

SIDs may include specific communications failure procedures. These specific procedures supersede the standard communication failure procedures.

SIDs, as published, will not contravene noise abatement procedures. ATC assigned vectors will not normally contravene noise abatement procedures, however, ATC may be required to issue a vector contrary to noise abatement for flight safety reasons.

ATC assigned vectors shall be followed in a timely manner even if they are in conflict with the published noise abatement procedures.

**CANADA
RULES AND PROCEDURES****SIMULTANEOUS RUNWAY OPERATIONS****Simultaneous Precision Instrument Approaches — Parallel Runways**

When simultaneous precision instrument approaches are in progress, ATC will vector arriving aircraft to one or the other of the parallel localizers for a straight-in final approach. (When cleared for a straight-in approach, a procedure turn is not permitted.) Each of the parallel approaches has a “high side” and a “low side” for vectoring and to allow for vertical separation until each aircraft is established inbound on their respective parallel localizers (LOC).

The pilot will be instructed to change and report on the tower frequency prior to reaching the final approach fix (FAF) inbound. If an aircraft is observed to overshoot the localizer during the final turn, the pilot will be instructed to return to the correct localizer course immediately. After an aircraft is established on the localizer, the controller monitoring the final approach will issue control instructions only if an aircraft deviates or is expected to deviate by 1500 feet from the localizer center line. Information or instructions issued by the monitoring controller will be aimed at returning the aircraft to the localizer course. If the aircraft fails to take corrective action, the aircraft on the adjacent localizer may be issued appropriate control instructions. Monitoring of the approach is terminated without notification to the pilot when the aircraft is 1 NM from the runway threshold. If considered necessary, appropriate missed approach instructions will be issued.

THE APPROACH CLEARANCE WILL INCLUDE AN ALTITUDE THAT MUST BE MAINTAINED UNTIL INTERCEPTING THE GLIDE PATH. If the glide path is inoperative, the pilot will be cleared to maintain an altitude to a specified DME distance before commencing descent.

When informed by ATIS or by the arrival controller that simultaneous precision instrument approaches are in progress, pilots shall advise the arrival controller immediately of any avionics unserviceabilities having an impact on their capabilities to accept this procedure.

Simultaneous Precision Instrument Approaches — Converging Runways

Aircraft will be informed through ATIS or by the arrival controller as soon as feasible after initial contact when simultaneous precision instrument approaches to converging runways are in progress. When simultaneous approaches are in progress, ATC will vector arriving aircraft to the appropriate runway localizer for a straight-in final approach. Pilots shall advise the arrival controller immediately of any malfunctioning or inoperative equipment making this procedure undesirable.

To emphasize the protection of active runways and to aid in preventing runway incursions, landing instructions which include the words “HOLD SHORT” should be acknowledged by a readback of the hold point by the pilot.

Operations on Intersecting Runways

ATC procedures allow for sequential and/or simultaneous operations on intersecting runways. Their intent is to increase airport traffic capacity, thus reducing delays and saving fuel. These operations differ only in the controllers’ application of ATC procedures; ATC advisories will specify the type of operation(s) in progress.

CANADA RULES AND PROCEDURES

General

ATC must include specific directions to hold short of an intersecting runway (e.g., “cleared to land Runway 27, hold short of Runway 36”). Pilots, in accepting the clearance, must read back “cleared to land Runway 27, hold short of Runway 36”. Having accepted the “hold short” clearance, *pilots are obligated to remain 200 ft short of the closest edge of the runway being intersected*. If, for any reason, a pilot is unsure of being able to comply with a “hold short” clearance, the pilot must advise ATC immediately of non-acceptance of the clearance; *it is far better to be safe than sorry*.

General Provisions

- All pilots will be advised that simultaneous Land and Hold Short Operations (LAHSO) are in progress.
- Controllers will issue appropriate traffic information.
- Acceptance of a “hold short” landing clearance indicates to the controller that a pilot is able to comply with the clearance. If for any reason a pilot elects to use the full length of a runway, or a different runway, the pilot should inform ATC on or before receipt of the “hold short” landing clearance.

NOTE: During sequential and/or simultaneous operations, ATC Procedures and pilot compliance with clearance conditions will ensure aircraft separation (i.e. spacing between aircraft). Notwithstanding this, conflicts between aircraft may occur, particularly at runway intersections, if a pilot does not comply with a clearance or is unable to comply as a result of unforeseen circumstances, such as missed approaches, misjudged landings, balked landings or brake failures. In these circumstances, ATC will endeavour to provide traffic advisories and/or instructions to assist pilots with collision avoidance.

ATS AIRSPACE CLASSIFICATION

Air traffic services (ATS) airspace classes in Canada conform to the ATS airspace classification table in Appendix 4 of Annex 11, “Air Traffic Services,” of the Convention on International Civil Aviation with the differences listed in “Differences from ICAO Standards and Procedures.”

Advisory Airspace

Airspace may be classified as Class “F” advisory airspace if it is airspace within which activity occurs that, for flight safety purposes, nonparticipating pilots should be aware of, such as training areas, parachute areas, hang gliding areas, military operations areas, etc.

Restricted Airspace

A restricted area is airspace of defined dimensions above the land areas or territorial waters within which the flight of aircraft is restricted in accordance with certain specified conditions. Restricted airspace is designated for safety purposes when the level or type of aerial activity, the surface activity, or the protection of a ground installation requires the application of restrictions within that airspace.

CANADA
RULES AND PROCEDURES

GLOBAL NAVIGATION SATELLITE SYSTEM (GNSS)

USE OF GNSS IN LIEU OF GROUND-BASED AIDS (GNSS SUBSTITUTION)

GNSS may be used in lieu of DME during departure/enroute/terminal/approach operations; it may be used in lieu of conventional (VOR and NDB) for departure/enroute/terminal operations provided the following conditions are met:

- an integrity alert is not displayed;
- fixes that are part of a terminal instrument procedure are named, charted and retrieved from a current navigation database; and
- when ATS requests a position based on a distance from a DME facility for separation purposes, reported GNSS distance from the same DME facility may be used by stating the distance in miles and the DME facility name (e.g. “30 miles from Sumspot VOR,” vice “30 DME from Sumspot VOR”).

GNSS may not be used in lieu of ground-based aids for:

- VOR and NDB final approach segment LNAV guidance on VOR- or NDB- instrument approach procedures unless the instrument approach procedure is part of the GNSS overlay approach program (see GNSS substitution examples); or
- LOC LNAV guidance (see GNSS substitution examples).

GNSS Substitution Examples

Approach Type	Failed Item	GNSS Substitution Allowed
NDB RWY 08R	Aircraft ADF* or approach NDB	No
NDB/DME RWY 08R	Aircraft DME or approach DME	Yes
NDB/DME RWY 08R (GNSS)	Aircraft ADF* or approach NDB	Yes
VOR RWY 09	Aircraft VHF Navigation or approach VOR	No
VOR/DME RWY 09 (GNSS)	Aircraft VHF Navigation or approach VOR	Yes
ILS Y RWY 16	Aircraft ADF*/DME or missed approach NAVAID	Yes

*ADF = automatic direction finder

CANADA RULES AND PROCEDURES

SPECIAL REQUIREMENTS AND REGULATIONS

ALTIMETRY

Altimeter Setting Procedures During Abnormally High Pressure Weather Conditions

Cold dry air masses can produce barometric pressures in excess of 31.00 inches of mercury. Because barometric readings of 31.00 inches of mercury or higher rarely occur, most standard altimeters do not permit setting of barometric pressures above that level and are not calibrated to indicate accurate aircraft altitude above 31.00 inches of mercury. As a result, most altimeters cannot be set to provide accurate altitude readouts to the pilot in these situations.

When aircraft operate in areas where the altimeter setting is in excess of 31.00 inches of mercury and the aircraft altimeter cannot be set above 31.00 inches of mercury, the true altitude of the aircraft will be HIGHER than the indicated altitude.

Cold Temperature Corrections

Pressure altimeters are calibrated to indicate true altitude under ISA conditions. Any deviation from ISA will result in an erroneous reading on the altimeter. In a case when the temperature is higher than ISA, the true altitude will be higher than the figure indicated by the altimeter and the true altitude will be lower when the temperature is lower than ISA. The altimeter error may be significant and becomes extremely important when considering obstacle clearances in very cold temperatures.

The published minimum IFR altitudes (i.e. the MSA/TAA and the initial/intermediate/final and missed approach segments, including the MDA/DA) must be adjusted when the ambient temperature on the surface is much lower than that predicted by the standard atmosphere. As a general rule this is considered to be 0°C or, when MDAs/DAs are 1000 ft HAA or higher, it begins at 10°C.

NOTE: Should the pilot feel that the above rules do not adequately adjust the published minimum IFR altitudes in the procedures to compensate for low temperatures, it is at the pilot's discretion to apply temperature correction whenever the airport temperature is below the ISA.

Corrections may be obtained from the "Altitude Correction Chart" (shown in ATC — INSTRUMENT FLIGHT RULES — ARRIVAL PROCEDURES — PROCEDURE ALTITUDES AND CURRENT ALTIMETER SETTING). This chart is calculated for an airport at sea level. It is, therefore, conservative when applied to airports at higher altitudes. To calculate the corrections (reduced altitudes) for specific airports or altimeter setting sources above sea level, or for values not tabulated, refer to the following paragraphs.

With respect to altitude corrections the following procedures apply:

- IFR assigned altitudes may be either accepted or refused. Refusal in this case is based upon the pilot's assessment of temperature effect on obstruction clearance. IFR assigned altitudes accepted by a pilot should not be adjusted to compensate for cold temperatures i.e. if a pilot accepts "maintain 3000," an altitude correction should not be applied to 3000 ft.
- Vectoring altitudes assigned by ATC are temperature corrected and require no temperature compensation by pilots.

CANADA RULES AND PROCEDURES

- c. When altitude corrections are applied to a published mandatory altitude or missed approach holding altitude, pilots should advise ATC of the temperature-corrected altitude prior to crossing the associated waypoint.

FUEL REQUIREMENTS

In addition to IFR fuel requirements, every aircraft shall carry an amount of fuel that is sufficient to provide for

- a. taxiing and foreseeable delays prior to takeoff;
- b. meteorological conditions;
- c. foreseeable air traffic routings and traffic delays;
- d. landing at a suitable airport in the event of loss of cabin pressurization or, in the case of a multi-engined aircraft, failure of any engine, at the most critical point during the flight; and
- e. any other foreseeable conditions that could delay the landing of the aircraft.

An aircraft operated in IFR flight shall carry an amount of fuel that is sufficient to allow the aircraft

- a. in the case of a propeller-driven airplane,
 - 1. where an alternate airport is specified in the flight plan or flight itinerary, to fly to and execute an approach and a missed approach at the destination airport, to fly to and land at the alternate airport, and then to fly for a period of 45 minutes, or
 - 2. where an alternate airport is not specified in the flight plan or flight itinerary, to fly to and execute an approach and a missed approach at the destination airport and then to fly for a period of 45 minutes; or
- b. in the case of a turbojet powered airplane or a helicopter,
 - 1. where an alternate airport is specified in the flight plan or flight itinerary, to fly to and execute an approach and a missed approach at the destination airport, to fly to and land at the alternate airport, and then to fly for a period of 30 minutes, or
 - 2. where an alternate airport is not specified in the flight plan or flight itinerary, to fly to and execute an approach and a missed approach at the destination airport and then to fly for a period of 30 minutes.

ADHERENCE TO MACH NUMBER

Within CDA, aircraft shall adhere to the Mach number assigned by ATC, to within 0.01 Mach, unless approval is obtained from ATC to make a change or until the pilot receives the initial descent clearance approaching destination. If it is necessary to make an immediate temporary change in the Mach number (e.g. because of turbulence), ATC shall be notified as soon as possible that such a change has been made.

If it is not possible, because of aircraft performance, to maintain the last assigned Mach number during enroute climbs and descents, pilots shall advise ATC at the time of the climb/descent request.

CANADA RULES AND PROCEDURES

AIRCRAFT GROUP NUMBER (AGN)

As a result of changes introduced to the TP312 5th Edition — AERODROME STANDARDS and RECOMMENDED PRACTICES, aeronautical publications will be updated to include information on the certification level of the various parts of the airport. This will be accomplished through the use of Aircraft Group Number or 'AGN' methodology. The purpose of AGN is to provide a simple method for relating key airport technical specifications with the characteristics of the critical aircraft for which the airport or part thereof is provided. These characteristics include:

- a. Wingspan (with consideration of the aircraft approach speed category);
- b. Outer main gear span; and
- c. Tail height.

NOTE: The outer main gear width is the aircraft characteristic relating to runway and taxiway widths, wingspan related to taxiway strip widths, and wingspan with an approach speed consideration related to runway strip and safety area widths.

An entry of "AGN IV" indicates that the runway is certified as meeting requirements with respect to the obstacle free environment to support the airborne and ground operation of aircraft having wingspans less than 52.12m (171 feet).

See the following table for a breakdown of wingspans into AGN groupings. The determination of the AGN is made with reference to the V_{ref} obtained with the airplane at maximum landing weight and configured with the maximum allowable landing flap. It does not include any operational adjustments to V_{ref} due to environmental conditions (steady state wind, gusts or icing, etc.) or aircraft abnormal or emergency configuration (slats or flaps jam, etc.).

Runway Obstacle Free Environment

Wing Span	Aircraft Group Number
Less than 14.94m (49')	I (for approach speed CAT C or D use AGN IIIB)
14.94m up to but not including 24.10m (79')	II (for approach speed CAT C or D use AGN IIIB)
24.10m up to but not including 36.00m (118')	IIIA (for approach speed CAT C or D use AGN IIIB)
24.10m up to but not including 36.00m (118')	IIIB (includes groups I – IIIA with C & D approach speeds)
36.00m up to but not including 52.12m (171')	IV
52.12m up to but not including 65.23m (214')	V
65.23m up to but not including 79.86m (262')	VI

**CANADA
RULES AND PROCEDURES**

Category	A or COPTER	B	C	D	E
Speeds	up to 90 kts	91 to 120 kts	121 to 140 kts	141 to 165 kts	above 165 kts

The AGN will only be published for those taxiways having a lower AGN than of the runway with the highest certification level.

See the following table for Taxiway AGN.

Taxiway Obstacle Free Environment

Wing Span	Aircraft Group Number
Less than 14.94m (49')	I
14.94m up to but not including 24.10m (79')	II
24.10m up to but not including 36.00m (118')	IIIA/IIIB
36.00m up to but not including 52.12m (171')	IV
52.12m up to but not including 65.23m (214')	V
65.23m up to but not including 79.86m (262')	VI

- d. An Aircraft Group Number is used to communicate the maximum aircraft wingspan and approach speed category for the part of a certified airport that is assessed.

SURVEILLANCE SERVICE IN THE NAT REGION

When crossing from one oceanic control center to the next outbound into the NAT, phraseology “Radar service is terminated” or “Surveillance service is terminated” may not be used anymore by ATC due to improved SSR equipment and ADS-B coverage.

DIFFERENCES FROM ICAO STANDARDS AND PROCEDURES

ICAO REFERENCE

ANNEX 11, AIR TRAFFIC SERVICES

Accident — Canada’s definition differs in that it does not make reference to unmanned aircraft.

Air Traffic Advisory Service — Advisory service refers to the provision of flight information.

Air Traffic Control Clearance — Canada also uses air traffic control instruction defined as a directive issued by an air traffic control unit for air traffic control purposes.

Altitude — Means the altitude indicated in an altimeter set to the current altimeter setting.

Apron Management Service — Not used in Canada.

Flight Level — An altimeter set to 29.92 inches of mercury, or 1013.2 millibars, is used.

INCERFA — Code word not used.

CANADA
RULES AND PROCEDURES

2.6.1

Class C — In Canada, in addition to the provisions of this paragraph, separation is provided between VFR aircraft at pilot request.

Class D — In Canada, workload and equipment permitting, these services are provided between IFR and VFR aircraft and between VFR aircraft at pilot request.

Class E — In Canada, some control zones are designated as Class E.

Class F — In Canada, Class F refers to special use airspace identified as restricted or advisory.

DOC 4444, PROCEDURES FOR AIR NAVIGATION SERVICES—AIR TRAFFIC MANAGEMENT (PANS-ATM)

5.4.2.3.4.2 Longitudinal separation minimum for aircraft on reciprocal tracks is 5 NM.

5.4.2.6.2.2 CPDLC as the sole means of DCPC is not permitted in the application of these distance-based longitudinal separations.

5.4.2.6.3 Longitudinal distance-based separation minimum in an RNPC environment using direct voice communication is 30 NM.

6.3.2.4 The phraseology CLIMB VIA SID is not used. Aircraft will be assigned a SID by having the procedure name included in their initial clearance followed by the word DEPARTURE. If the assigned altitude is different from the SID altitude, the aircraft will be notified using the phraseology CLIMB TO AMENDED ALTITUDE (*altitude or flight level*).

6.5.2.4.1 The phraseology DESCEND VIA STAR is not used. Aircraft are assigned a specified STAR as part of their route clearance and will be cleared to appropriate altitudes in the descent and approach phases of flight.

8.7.3.4 The wake turbulence radar separation minimum for a MEDIUM preceding aircraft and a LIGHT succeeding aircraft is 4 NM.

12.3.1.8 Altimeter settings are issued using the phraseology ALTIMETER (*setting*). Altimeter settings are issued in QNH (height above sea level).

12.3.1.14 GNSS service status phraseology is not used.

12.3.4.6 Altimeter settings are issued using the phraseology ALTIMETER (*setting*). Altimeter settings are issued in QNH (height above sea level).

12.3.4.7 Taxi procedures phraseology does not use “HOLDING POSITION/POINT.”

12.3.4.13 Altimeter settings are issued using the phraseology ALTIMETER (*setting*). Altimeter settings are issued in QNH (height above sea level).

12.3.4.20 Standard runway vacating phraseology is not used. Plain language is used instead.

12.6.1.1 Altimeter settings are issued using the phraseology ALTIMETER (*setting*). Altimeter settings are issued in QNH (height above sea level).

15.3.3 The aircraft having the communication failure will maintain the route and altitude assigned in the last ATC clearance that was received and acknowledged, unless operating below

CANADA
RULES AND PROCEDURES

the published minimum IFR altitude. Two-way communications failure procedures are published in the *Canada Flight Supplement* (not published herein).

Air Traffic Control

State Rules and Procedures -
United States

US 2-1

SECTION 1. AIRPORT LIGHTING AIDS

2-1-1 APPROACH LIGHT SYSTEMS (ALS)

- a. ALS provide the basic means to transition from instrument flight to visual flight for landing. Operational requirements dictate the sophistication and configuration of the approach light system for a particular runway.
- b. ALS are a configuration of signal lights starting at the landing threshold and extending into the approach area a distance of 2400-3000 feet for precision instrument runways and 1400-1500 feet for nonprecision instrument runways. Some systems include sequenced flashing lights which appear to the pilot as a ball of light traveling towards the runway at high speed (twice a second). (See FIG 2-1-1.)

2-1-2 VISUAL GLIDESLOPE INDICATORS**a. Visual Approach Slope Indicator (VASI)**

1. VASI installations may consist of either 2, 4, 6, 12, or 16 light units arranged in bars referred to as near, middle, and far bars. Most VASI installations consist of 2 bars, near and far, and may consist of 2, 4, or 12 light units. Some VASIs consist of three bars, near, middle, and far, which provide an additional visual glide path to accommodate high cockpit aircraft. This installation may consist of either 6 or 16 light units. VASI installations consisting of 2, 4, or 6 light units are located on one side of the runway, usually the left. Where the installation consists of 12 or 16 light units, the units are located on both sides of the runway.
2. Two-bar VASI installations provide one visual glide path which is normally set at 3 degrees. Three-bar VASI installations provide two visual glide paths. The lower glide path is provided by the near and middle bars and is normally set at 3 degrees while the upper glide path, provided by the middle and far bars, is normally 1/4 degree higher. This higher glide path is intended for use only by high cockpit aircraft to provide a sufficient threshold crossing height. Although normal glide path angles are three degrees, angles at some locations may be as high as 4.5 degrees to give proper obstacle clearance. Pilots of high performance aircraft are cautioned that use of VASI angles in excess of 3.5 degrees may cause an increase in runway length required for landing and rollout.
3. The basic principle of the VASI is that of color differentiation between red and white. Each light unit projects a beam of light having a white segment in the upper part of the beam and red segment in the lower part of the beam. The light units are arranged so that the pilot using the VASIs during an approach will see the combination of lights shown below.
4. The VASI is a system of lights so arranged to provide visual descent guidance information during the approach to a runway. These lights are visible from 3–5 miles during the day and up to 20 miles or more at night. The visual glide path of the VASI provides safe obstruction clearance within plus or minus 10 degrees of the extended runway centerline and to 4 NM from the runway threshold. Descent, using the VASI, should not be initiated until the aircraft is visually aligned with the runway. Lateral course guidance is

US 2-1**SECTION 1. AIRPORT LIGHTING AIDS**

provided by the runway or runway lights. In certain circumstances, the safe obstruction clearance area may be reduced by narrowing the beam width or shortening the usable distance due to local limitations, or the VASI may be offset from the extended runway centerline. This will be noted in the Chart Supplement U.S. and/or applicable Notices to Air Missions (NOTAMs).

US 2-1

3-Bar VASI

7. For other VASI configurations see FIG 2-1-4.

FIGURE 2-1-4

VASI Variations

US 2-1

SECTION 1. AIRPORT LIGHTING AIDS

- b. **Precision Approach Path Indicator (PAPI).** The precision approach path indicator (PAPI) uses light units similar to the VASI but are installed in a single row of either two or four light units. These lights are visible from about 5 miles during the day and up to 20 miles at night. The visual glide path of the PAPI typically provides safe obstruction clearance within plus or minus 10 degrees of the extended runway centerline and to 3.4 NM from the runway threshold. Descent, using the PAPI, should not be initiated until the aircraft is visually aligned with the runway. The row of light units is normally installed on the left side of the runway and the glide path indications are as depicted. Lateral course guidance is provided by the runway or runway lights. In certain circumstances, the safe obstruction clearance area may be reduced by narrowing the beam width or shortening the usable distance due to local limitations, or the PAPI may be offset from the extended runway centerline. This will be noted in the Chart Supplement U.S. and/or applicable NOTAMS. (See FIG 2-1-5.)

FIGURE 2-1-5

Precision Approach Path Indicator (PAPI)

- c. **Tri-color Systems.** Tri-color visual approach slope indicators normally consist of a single light unit projecting a three-color visual approach path into the final approach area of the runway upon which the indicator is installed. The below glide path indication is red, the above glide path indication is amber, and the on glide path indication is green. These types of indicators have a useful range of approximately one-half to one mile during the day and up to five miles at night depending upon the visibility conditions. (See FIG 2-1-6.)

US 2-1

SECTION 1. AIRPORT LIGHTING AIDS

FIGURE 2-1-6

Tri-Color Visual Approach Slope Indicator

NOTE:

1. Since the tri-color VASI consists of a single light source which could possibly be confused with other light sources, pilots should exercise care to properly locate and identify the light signal.
2. When the aircraft descends from green to red, the pilot may see a dark amber color during the transition from green to red.

FIGURE 2-1-7

PULSATING VISUAL APPROACH SLOPE INDICATOR

NOTE: Since the PVASI consists of a single light source which could possibly be confused with other light sources, pilots should exercise care to properly locate and identify the light signal.

US 2-1
SECTION 1. AIRPORT LIGHTING AIDS

FIGURE 2-1-8

Alignment of Elements

- d. **Pulsating Systems.** Pulsating visual approach slope indicators normally consist of a single light unit projecting a two-color visual approach path into the final approach area of the runway upon which the indicator is installed. The on glide path indication may be a steady white light or alternating RED and WHITE light. The slightly below glide path indication is a steady red light. If the aircraft descends further below the glide path, the red light starts to pulsate. The above glide path indication is a pulsating white light. The pulsating rate increases as the aircraft gets further above or below the desired glide slope. The useful range of the system is about four miles during the day and up to ten miles at night. (See FIG 2-1-7.)
- e. **Alignment of Elements Systems.** Alignment of elements systems are installed on some small general aviation airports and are a low-cost system consisting of painted plywood panels, normally black and white or fluorescent orange. Some of these systems are lighted for night use. The useful range of these systems is approximately three-quarter miles. To use the system the pilot positions the aircraft so the elements are in alignment. The glide path indications are shown in FIG 2-1-8.

2-1-3 RUNWAY END IDENTIFIER LIGHTS (REIL)

REILs are installed at many airfields to provide rapid and positive identification of the approach end of a particular runway. The system consists of a pair of synchronized flashing lights located laterally on each side of the runway threshold. REILs may be either omnidirectional or unidirectional facing the approach area. They are effective for:

- Identification of a runway surrounded by a preponderance of other lighting.
- Identification of a runway which lacks contrast with surrounding terrain.
- Identification of a runway during reduced visibility.

2-1-4 RUNWAY EDGE LIGHT SYSTEMS

- Runway edge lights are used to outline the edges of runways during periods of darkness or restricted visibility conditions. These light systems are classified according to the intensity or

US 2-1

SECTION 1. AIRPORT LIGHTING AIDS

brightness they are capable of producing: they are the High Intensity Runway Lights (HIRL), Medium Intensity Runway Lights (MIRL), and the Low Intensity Runway Lights (LIRL). The HIRL and MIRL systems have variable intensity controls, whereas the LIRLs normally have one intensity setting.

- b. The runway edge lights are white, except on instrument runways yellow replaces white on the last 2,000 feet or half the runway length, whichever is less, to form a caution zone for landings.
- c. The lights marking the ends of the runway emit red light toward the runway to indicate the end of runway to a departing aircraft and emit green outward from the runway end to indicate the threshold to landing aircraft.

2-1-5 IN-RUNWAY LIGHTING

- a. **Runway Centerline Lighting System (RCLS).** Runway centerline lights are installed on some precision approach runways to facilitate landing under adverse visibility conditions. They are located along the runway centerline and are spaced at 50-foot intervals. When viewed from the landing threshold, the runway centerline lights are white until the last 3,000 feet of the runway. The white lights begin to alternate with red for the next 2,000 feet, and for the last 1,000 feet of the runway, all centerline lights are red.
- b. **Touchdown Zone Lights (TDZL).** Touchdown zone lights are installed on some precision approach runways to indicate the touchdown zone when landing under adverse visibility conditions. They consist of two rows of transverse light bars disposed symmetrically about the runway centerline. The system consists of steady-burning white lights which start 100 feet beyond the landing threshold and extend to 3,000 feet beyond the landing threshold or to the midpoint of the runway, whichever is less.
- c. **Taxiway Centerline Lead-Off Lights.** Taxiway centerline lead-off lights provide visual guidance to persons exiting the runway. They are color-coded to warn pilots and vehicle drivers that they are within the runway environment or instrument landing system (ILS) critical area, whichever is more restrictive. Alternate green and yellow lights are installed, beginning with green, from the runway centerline to one centerline light position beyond the runway holding position or ILS critical area holding position.
- d. **Taxiway Centerline Lead-On Lights.** Taxiway centerline lead-on lights provide visual guidance to persons entering the runway. These "lead-on" lights are also color-coded with the same color pattern as lead-off lights to warn pilots and vehicle drivers that they are within the runway environment or instrument landing system (ILS) critical area, whichever is more conservative. The fixtures used for lead-on lights are bidirectional, i.e., one side emits light for the lead-on function while the other side emits light for the lead-off function. Any fixture that emits yellow light for the lead-off function must also emit yellow light for the lead-on function. (See FIG 2-1-12.)
- e. **Land and Hold Short Lights.** Land and hold short lights are used to indicate the hold short point on certain runways which are approved for Land and Hold Short Operations (LAHSO). Land and hold short lights consist of a row of pulsing white lights installed across the runway

US 2-1

SECTION 1. AIRPORT LIGHTING AIDS

at the hold short point. Where installed, the lights will be on anytime LAHSO is in effect. These lights will be off when LAHSO is not in effect.

REFERENCE—AIM, Paragraph 4-3-11, *Pilot Responsibilities When Conducting Land and Hold Short Operations (LAHSO)*.

2-1-6 RUNWAY STATUS LIGHT (RWSL) SYSTEM

a. Introduction.

RWSL is a fully automated system that provides runway status information to pilots and surface vehicle operators to clearly indicate when it is unsafe to enter, cross, takeoff from, or land on a runway. The RWSL system processes information from surveillance systems and activates Runway Entrance Lights (REL) and Takeoff Hold Lights (THL), in accordance with the position and velocity of the detected surface traffic and approach traffic. REL and THL are in-pavement light fixtures that are directly visible to pilots and surface vehicle operators. RWSL is an independent safety enhancement that does not substitute for or convey an ATC clearance. Clearance to enter, cross, takeoff from, land on, or operate on a runway must still be received from ATC. Although ATC has limited control over the system, personnel do not directly use and may not be able to view light fixture activations and deactivations during the conduct of daily ATC operations.

- b. Runway Entrance Lights (REL): The REL system is composed of flush mounted, in-pavement, unidirectional light fixtures that are parallel to and focused along the taxiway centerline and directed toward the pilot at the hold line. An array of REL lights include the first light at the hold line followed by a series of evenly spaced lights to the runway edge; one additional light at the runway centerline is in line with the last two lights before the runway edge (see FIG 2-1-9 and FIG 2-1-10). When activated, the red lights indicate that there is high speed traffic on the runway or there is an aircraft on final approach within the activation area.

US 2-1
SECTION 1. AIRPORT LIGHTING AIDS

FIG 2-1-9

Runway Status Light System

1. REL Operating Characteristics – Departing Aircraft:

When a departing aircraft reaches a site adaptable speed of approximately 30 knots, all taxiway intersections with REL arrays along the runway ahead of the aircraft will illuminate (see FIG 2-1-9). As the aircraft approaches an REL equipped taxiway intersection, the lights at that intersection extinguish approximately 3 to 4 seconds before the aircraft reaches it. This allows controllers to apply “anticipated separation” to permit ATC to move traffic more expeditiously without compromising safety. After the aircraft is declared “airborne” by the system, all REL lights associated with this runway will extinguish.

2. REL Operating Characteristics – Arriving Aircraft:

When an aircraft on final approach is approximately 1 mile from the runway threshold, all sets of taxiway REL light arrays that intersect the runway illuminate. The distance is adjustable and can be configured for specific operations at particular airports. Lights extinguish at each equipped taxiway intersection approximately 3 to 4 seconds before

US 2-1

SECTION 1. AIRPORT LIGHTING AIDS

the aircraft reaches it to apply anticipated separation until the aircraft has slowed to approximately 80 knots (site adjustable parameter). Below 80 knots, all arrays that are not within 30 seconds of the aircraft's forward path are extinguished. Once the arriving aircraft slows to approximately 34 knots (site adjustable parameter), it is declared to be in a taxi state, and all lights extinguish.

3. What a pilot would observe: A pilot at or approaching the hold line to a runway will observe RELs illuminate and extinguish in reaction to an aircraft or vehicle operating on the runway, or an arriving aircraft operating less than 1 mile from the runway threshold.
 4. When a pilot observes the red lights of the REL, that pilot will stop at the hold line or remain stopped. The pilot will then contact ATC for resolution if the clearance is in conflict with the lights. Should pilots note illuminated lights under circumstances when remaining clear of the runway is impractical for safety reasons (for example, aircraft is already on the runway), the crew should proceed according to their best judgment while understanding the illuminated lights indicate the runway is unsafe to enter or cross. Contact ATC at the earliest possible opportunity.
- c. Takeoff Hold Lights (THL): The THL system is composed of flush mounted, in-pavement, unidirectional fixtures in a double longitudinal row aligned either side of the runway centerline lighting. Fixtures are focused toward the arrival end of the runway at the "line up and wait" point. THLs extend for 1,500 feet in front of the holding aircraft starting at a point 375 feet from the departure threshold (see FIG 2-1-11). Illuminated red lights provide a signal, to an aircraft in position for takeoff or rolling, that it is unsafe to takeoff because the runway is occupied or about to be occupied by another aircraft or ground vehicle. Two aircraft, or a surface vehicle and an aircraft, are required for the lights to illuminate. The departing aircraft must be in position for takeoff or beginning takeoff roll. Another aircraft or a surface vehicle must be on or about to cross the runway.

1. THL Operating Characteristics - Departing Aircraft:

THLs will illuminate for an aircraft in position for departure or departing when there is another aircraft or vehicle on the runway or about to enter the runway (see FIG 2-1-9). Once that aircraft or vehicle exits the runway, the THLs extinguish. A pilot may notice lights extinguish prior to the downfield aircraft or vehicle being completely clear of the runway but still moving. Like RELs, THLs have an "anticipated separation" feature.

NOTE: When the THLs extinguish, this is not clearance to begin a takeoff roll. All take-off clearances will be issued by ATC.

2. What a pilot would observe: A pilot in position to depart from a runway, or has begun takeoff roll, will observe THLs illuminate in reaction to an aircraft or vehicle on the runway or entering or crossing it. Lights will extinguish when the runway is clear. A pilot may observe several cycles of illumination and extinguishing depending on the amount of crossing traffic.
3. When a pilot observes the red light of the THLs, the pilot should safely stop if it's feasible or remain stopped. The pilot must contact ATC for resolution if any clearance is in conflict with the lights. Should pilots note illuminated lights while in takeoff roll and under

US 2-1

SECTION 1. AIRPORT LIGHTING AIDS

circumstances when stopping is impractical for safety reasons, the crew should proceed according to their best judgment while understanding the illuminated lights indicate that continuing the takeoff is unsafe. Contact ATC at the earliest possible opportunity.

d. Pilot Actions:

1. When operating at airports with RWSL, pilots will operate with the transponder/ADS-B "On" when departing the gate or parking area until it is shut down upon arrival at the gate or parking area. This ensures interaction with the FAA surveillance systems such as ASDE-X/Airport Surface Surveillance Capability (ASSC) which provide information to the RWSL system.
2. Pilots must always inform the ATCT when they have stopped due to an RWSL indication that is in conflict with ATC instructions. Pilots must request clarification of the taxi or takeoff clearance.
3. Never cross over illuminated red lights. Under normal circumstances, RWSL will confirm the pilot's taxi or takeoff clearance previously issued by ATC. If RWSL indicates that it is unsafe to takeoff from, land on, cross, or enter a runway, immediately notify ATC of the conflict and re-confirm the clearance.
4. Do not proceed when lights have extinguished without an ATC clearance. RWSL verifies an ATC clearance, it does not substitute for an ATC clearance.
5. Never land if PAPI continues to flash. Execute a go around and notify ATC.

e. ATC Control of RWSL System:

1. Controllers can set in-pavement lights to one of five (5) brightness levels to assure maximum conspicuity under all visibility and lighting conditions. REL and THL subsystems may be independently set.
2. System lights can be disabled should RWSL operations impact the efficient movement of air traffic or contribute, in the opinion of the assigned ATC Manager, to unsafe operations. REL and THL light fixtures may be disabled separately. Whenever the system or a component is disabled, a NOTAM must be issued, and the Automatic Terminal Information System (ATIS) must be updated.

2-1-7 CONTROL OF LIGHTING SYSTEMS

- a. Operation of approach light systems and runway lighting is controlled by the control tower (ATCT). At some locations the FSS may control the lights where there is no control tower in operation.
- b. Pilots may request that lights be turned on or off. Runway edge lights, in-pavement lights and approach lights also have intensity controls which may be varied to meet the pilots request. Sequenced flashing lights (SFL) may be turned on and off. Some sequenced flashing light systems also have intensity control.

US 2-1

SECTION 1. AIRPORT LIGHTING AIDS

2-1-8 PILOT CONTROL OF AIRPORT LIGHTING

Radio control of lighting is available at selected airports to provide airborne control of lights by keying the aircraft's microphone. Control of lighting systems is often available at locations without specified hours for lighting and where there is no control tower or FSS or when the tower or FSS is closed (locations with a part-time tower or FSS) or specified hours. All lighting systems which are radio controlled at an airport, whether on a single runway or multiple runways, operate on the same radio frequency. (See TBL 2-1-1 and TBL 2-1-2.)

HIRL	5	Off or Low	♦	♦	♦
VASI	2	Off	*	*	*

NOTES: ♦Predetermined intensity step.

*Low intensity for night use. High intensity for day use as determined by photocell control.

US 2-1
SECTION 1. AIRPORT LIGHTING AIDS

TABLE 2-1-2 Runways Without Approach Lights

Lighting System	No. of Int. Steps	Status During Nonuse Period	Intensity Step Selected Per No. of Mike Clicks		
			3 Clicks	5 Clicks	7 Clicks
MIRL	3	Off or Low	Low	Med.	High
HIRL	5	Off or Low	Step 1 or 2	Step 3	Step 5
LIRL	1	Off	On	On	On
VASI*	2	Off	♦	♦	♦
REIL*	1	Off	Off	On /Off	On
REIL*	3	Off	Low	Med.	High

NOTES: ♦Low intensity for night use. High intensity for day use as determined by photocell control.

*The control of VASI and/or REIL may be independent of other lighting systems.

- With FAA approved systems, various combinations of medium intensity approach lights, runway lights, taxiway lights, VASI and/or REIL may be activated by radio control. On runways with both approach lighting and runway lighting (runway edge lights, taxiway lights, etc.) systems, the approach lighting system takes precedence for air-to-ground radio control over the runway lighting system which is set at a predetermined intensity step, based on expected visibility conditions. Runways without approach lighting may provide radio controlled intensity adjustments of runway edge lights. Other lighting systems, including VASI, REIL, and taxiway lights may be either controlled with the runway edge lights or controlled independently of the runway edge lights.
- The control system consists of a 3-step control responsive to 7, 5, and/or 3 microphone clicks. This 3-step control will turn on lighting facilities capable of either 3-step, 2-step or 1-step operation. The 3-step and 2-step lighting facilities can be altered in intensity, while the 1-step cannot. All lighting is illuminated for a period of 15 minutes from the most recent time of activation and may not be extinguished prior to end of the 15 minute period (except for 1-step and 2-step REILs which may be turned off when desired by keying the mike 5 or 3 times respectively).
- Suggested use is to always initially key the mike 7 times; this assures that all controlled lights are turned on to the maximum available intensity. If desired, adjustment can then be made, where the capability is provided, to a lower intensity (or the REIL turned off) by keying 5 and/or 3 times. Due to the close proximity of airports using the same frequency, radio controlled lighting receivers may be set at a low sensitivity requiring the aircraft to be relatively close to activate the system. Consequently, even when lights are on, always key mike as directed when overflying an airport of intended landing or just prior to entering the final segment of an approach. This will assure the aircraft is close enough to activate the system and

US 2-1
SECTION 1. AIRPORT LIGHTING AIDS

a full 15 minutes lighting duration is available. Approved lighting systems may be activated by keying the mike (within 5 seconds) as indicated in TBL 2-1-3.

TABLE 2-1-3 Radio Control System

Key Mike	Function
7 times within 5 seconds	Highest intensity available
5 times within 5 seconds	Medium or lower intensity (Lower REIL or REIL-off)
3 times within 5 seconds	Lowest intensity available (Lower REIL or REIL-off)

- d. For all public use airports with FAA standard systems the Chart Supplement U.S. contains the types of lighting, runway and the frequency that is used to activate the system. Airports with IAPs include data on the approach chart identifying the light system, the runway on which they are installed, and the frequency that is used to activate the system.

NOTE: *Although the CTAF is used to activate the lights at many airports, other frequencies may also be used. The appropriate frequency for activating the lights on the airport is provided in the Chart Supplement U.S. and the standard instrument approach procedures publications. It is not identified on the sectional charts. [See Jeppesen Approach Charts, Airport Directory, and JeppGuide]*

- e. Where the airport is not served by an IAP, it may have either the standard FAA approved control system or an independent type system of different specification installed by the airport sponsor. The Chart Supplement U.S. [and Jeppesen Airport Directory] contains descriptions of pilot controlled lighting systems for each airport having other than FAA approved systems, and explains the type lights, method of control, and operating frequency in clear text.

2-1-9 AIRPORT/HELIPORT BEACONS

- a. Airport and heliport beacons have a vertical light distribution to make them most effective from one to ten degrees above the horizon; however, they can be seen well above and below this peak spread. The beacon may be an omnidirectional capacitor-discharge device, or it may rotate at a constant speed which produces the visual effect of flashes at regular intervals. Flashes may be one or two colors alternately. The total number of flashes are:
1. 24 to 30 per minute for beacons marking airports, landmarks, and points on Federal airways.
 2. 30 to 45 per minute for beacons marking heliports.
- b. The colors and color combinations of beacons are:
1. White and Green- Lighted land airport.
 2. *Green alone- Lighted land airport.
 3. White and Yellow- Lighted water airport.

US 2-1

SECTION 1. AIRPORT LIGHTING AIDS

4. *Yellow alone- Lighted water airport.
5. Green, Yellow, and White- Lighted heliport.

NOTE: **Green alone or yellow alone is used only in connection with a white-and-green or white-and-yellow beacon display, respectively.*

- c. Military airport beacons flash alternately white and green, but are differentiated from civil beacons by dualpeaked (two quick) white flashes between the green flashes.
- d. In Class B, Class C, Class D and Class E surface areas, operation of the airport beacon during the hours of daylight often indicates that the ground visibility is less than 3 miles and/or the ceiling is less than 1,000 feet. ATC clearance in accordance with 14 CFR Part 91 is required for landing, takeoff and flight in the traffic pattern. Pilots should not rely solely on the operation of the airport beacon to indicate if weather conditions are IFR or VFR. At some locations with operating control towers, ATC personnel turn the beacon on or off when controls are in the tower. At many airports the airport beacon is turned on by a photoelectric cell or time clocks and ATC personnel can not control them. There is no regulatory requirement for daylight operation and it is the pilot's responsibility to comply with proper preflight planning as required by 14 CFR Section 91.103.

2-1-10 TAXIWAY LIGHTS

- a. **Taxiway Edge Lights.** Taxiway edge lights are used to outline the edges of taxiways during periods of darkness or restricted visibility conditions. These fixtures emit blue light.

NOTE: *At most major airports these lights have variable intensity settings and may be adjusted at pilot request or when deemed necessary by the controller.*

- b. **Taxiway Centerline Lights.** Taxiway centerline lights are used to facilitate ground traffic under low visibility conditions. They are located along the taxiway centerline in a straight line on straight portions, on the centerline of curved portions, and along designated taxiing paths in portions of runways, ramp, and apron areas. Taxiway centerline lights are steady burning and emit green light.
- c. **Clearance Bar Lights.** Clearance bar lights are installed at holding positions on taxiways in order to increase the conspicuity of the holding position in low visibility conditions. They may also be installed to indicate the location of an intersecting taxiway during periods of darkness. Clearance bars consist of three in-pavement steady-burning yellow lights.
- d. **Runway Guard Lights.** Runway guard lights are installed at taxiway/runway intersections. They are primarily used to enhance the conspicuity of taxiway/runway intersections during low visibility conditions, but may be used in all weather conditions. Runway guard lights consist of either a pair of elevated flashing yellow lights installed on either side of the taxiway, or a row of in-pavement yellow lights installed across the entire taxiway, at the runway holding position marking.

NOTE: *Some airports may have a row of three or five in-pavement yellow lights installed at taxiway/runway intersections. They should not be confused with clearance bar lights described in paragraph 2-1-10c, Clearance Bar Lights.*

US 2-1

SECTION 1. AIRPORT LIGHTING AIDS

- e. **Stop Bar Lights.** Stop bar lights, when installed, are used to confirm the ATC clearance to enter or cross the active runway in low visibility conditions (below 1,200 ft Runway Visual Range). A stop bar consists of a row of red, unidirectional, steady-burning in-pavement lights installed across the entire taxiway at the runway holding position, and elevated steady-burning red lights on each side. A controlled stop bar is operated in conjunction with the taxiway centerline lead-on lights which extend from the stop bar toward the runway. Following the ATC clearance to proceed, the stop bar is turned off and the lead-on lights are turned on. The stop bar and lead-on lights are automatically reset by a sensor or backup timer.

CAUTION: *Pilots should never cross a red illuminated stop bar, even if an ATC clearance has been given to proceed onto or across the runway.*

NOTE: *If after crossing a stop bar, the taxiway centerline lead-on lights inadvertently extinguish, pilots should hold their position and contact ATC for further instructions.*

US 2-2

SECTION 2. AIR NAVIGATION AND OBSTRUCTION LIGHTING

2-2-1 AERONAUTICAL LIGHT BEACONS

- a. An aeronautical light beacon is a visual NAVAID displaying flashes of white and/or colored light to indicate the location of an airport, a heliport, a landmark, a certain point of a Federal airway in mountainous terrain, or an obstruction. The light used may be a rotating beacon or one or more flashing lights. The flashing lights may be supplemented by steady burning lights of lesser intensity.
- b. The color or color combination displayed by a particular beacon and/or its auxiliary lights tell whether the beacon is indicating a landing place, landmark, point of the Federal airways, or an obstruction. Coded flashes of the auxiliary lights, if employed, further identify the beacon site.

2-2-2 CODE BEACONS AND COURSE LIGHTS

- a. **Code Beacons.** The code beacon, which can be seen from all directions, is used to identify airports and landmarks. The code beacon flashes the three or four character airport identifier in International Morse Code six to eight times per minute. Green flashes are displayed for land airports while yellow flashes indicate water airports.
- b. **Course Lights.** The course light, which can be seen clearly from only one direction, is used only with rotating beacons of the Federal Airway System: two course lights, back to back, direct coded flashing beams of light in either direction along the course of airway.

NOTE: *Airway beacons are remnants of the "lighted" airways which antedated the present electronically equipped federal airways system. Only a few of these beacons exist today to mark airway segments in remote mountain areas. Flashes in Morse code identify the beacon site.*

2-2-3 OBSTRUCTION LIGHTS

- a. Obstructions are marked/lighted to warn airmen of their presence during daytime and nighttime conditions. They may be marked/lighted in any of the following combinations:
 1. **Aviation Red Obstruction Lights.** Flashing aviation red beacons (20 to 40 flashes per minute) and steady burning aviation red lights during nighttime operation. Aviation orange and white paint is used for daytime marking.
 2. **Medium Intensity Flashing White Obstruction Lights.** Medium intensity flashing white obstruction lights may be used during daytime and twilight with automatically selected reduced intensity for nighttime operation. When this system is used on structures 500 feet (153m) AGL or less in height, other methods of marking and lighting the structure may be omitted. Aviation orange and white paint is always required for daytime marking on structures exceeding 500 feet (153m) AGL. This system is not normally installed on structures less than 200 feet (61m) AGL.
 3. **High Intensity White Obstruction Lights.** Flashing high intensity white lights during daytime with reduced intensity for twilight and nighttime operation. When this type system is used, the marking of structures with red obstruction lights and aviation orange and white paint may be omitted.

US 2-2

SECTION 2. AIR NAVIGATION AND OBSTRUCTION LIGHTING

4. **Dual Lighting.** A combination of flashing aviation red beacons and steady burning aviation red lights for nighttime operation and flashing high intensity white lights for daytime operation. Aviation orange and white paint may be omitted.
5. **Catenary Lighting.** Lighted markers are available for increased night conspicuity of high-voltage (69KV or higher) transmission line catenary wires. Lighted markers provide conspicuity both day and night.
 - b. Medium intensity omnidirectional flashing white lighting system provides conspicuity both day and night on catenary support structures. The unique sequential/simultaneous flashing light system alerts pilots of the associated catenary wires.
 - c. High intensity flashing white lights are being used to identify some supporting structures of overhead transmission lines located across rivers, chasms, gorges, etc. These lights flash in a middle, top, lower light sequence at approximately 60 flashes per minute. The top light is normally installed near the top of the supporting structure, while the lower light indicates the approximate lower portion of the wire span. The lights are beamed towards the companion structure and identify the area of the wire span.
 - d. High intensity flashing white lights are also employed to identify tall structures, such as chimneys and towers, as obstructions to air navigation. The lights provide a 360 degree coverage about the structure at 40 flashes per minute and consist of from one to seven levels of lights depending upon the height of the structure. Where more than one level is used the vertical banks flash simultaneously.

2-2-4 LED LIGHTING SYSTEMS

Certain light-emitting diode (LED) lighting systems fall outside the combined visible and near-infrared spectrum of night vision goggles (NVGs) and thus will not be visible to a flightcrew using NVGs.

The FAA changed specifications for LED-based red obstruction lights to make them visible to pilots using certain NVG systems, however, other colors may not be visible.

It is recommended that air carriers/operators — including Part 91 operators — who use NVGs incorporate procedures into manuals and/or standard operating procedures (SOPs) requiring periodic, unaided scanning when operating at low altitudes and when performing a reconnaissance of landing areas.

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

2-3-1 GENERAL

- a. Airport pavement markings and signs provide information that is useful to a pilot during take-off, landing, and taxiing.
- b. Uniformity in airport markings and signs from one airport to another enhances safety and improves efficiency. Pilots are encouraged to work with the operators of the airports they use to achieve the marking and sign standards described in this section.
- c. Pilots who encounter ineffective, incorrect, or confusing markings or signs on an airport should make the operator of the airport aware of the problem. These situations may also be reported under the Aviation Safety Reporting Program as described in Paragraph 7-7-1, Aviation Safety Reporting Program. Pilots may also report these situations to the FAA regional airports division.
- d. The markings and signs described in this section of the AIM reflect the current FAA recommended standards.

REFERENCE—

AC 150/5340-1, Standards for Airport Markings.

AC 150/5340-18, Standards for Airport Sign Systems.

2-3-2 AIRPORT PAVEMENT MARKINGS

- a. **General.** For the purpose of this section, the airport pavement markings have been grouped into four areas:
 1. **Runway Markings.**
 2. **Taxiway Markings.**
 3. **Holding Position Markings.**
 4. **Other Markings.**
- b. **Marking Colors.** Markings for runways are white. Markings defining the landing area on a heliport are also white except for hospital heliports which use a red “H” on a white cross. Markings for taxiways, areas not intended for use by aircraft (closed and hazardous areas), and holding positions (even if they are on a runway) are yellow.

2-3-3 RUNWAY MARKINGS

- a. **General.** There are three types of markings for runways: visual, nonprecision instrument, and precision instrument. TBL 2-3-1 identifies the marking elements for each type of runway and TBL 2-3-2 identifies runway threshold markings.

US 2-3
SECTION 3. AIRPORT MARKING AIDS AND SIGNS
TABLE 2-3-1 Runway Marking Elements

Marking Element	Visual Runway	Nonprecision Instrument Runway	Precision Instrument Runway
Designation	X	X	X
Centerline	X	X	X
Threshold	X ¹	X	X
Aiming Point	X ²	X	X
Touchdown Zone			X
Side Stripes			X

¹ On runways used, or intended to be used, by international commercial transports.

² On runways 4,000 feet (1200 m) or longer used by jet aircraft.

US 2-3
SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-1

Precision Instrument Runway Markings

- b. **Runway Designators.** Runway numbers and letters are determined from the approach direction. The runway number is the whole number nearest one-tenth the magnetic azimuth of the centerline of the runway, measured clockwise from the magnetic north. The letters, differentiate between left (L), right (R), or center (C) parallel runways, as applicable:
1. For two parallel runways "L" "R."
 2. For three parallel runways "L" "C" "R."
- c. **Runway Centerline Marking.** The runway centerline identifies the center of the runway and provides alignment guidance during takeoff and landings. The centerline consists of a line of uniformly spaced stripes and gaps.
- d. **Runway Aiming Point Marking.** The aiming point marking serves as a visual aiming point for a landing aircraft. These two rectangular markings consist of a broad white stripe located on each side of the runway centerline and approximately 1,000 feet from the landing threshold, as shown in FIG 2-3-1, Precision Instrument Runway Markings.

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

- e. **Runway Touchdown Zone Markers.** The touchdown zone markings identify the touchdown zone for landing operations and are coded to provide distance information in 500 feet (150 m) increments. These markings consist of groups of one, two, and three rectangular bars symmetrically arranged in pairs about the runway centerline, as shown in FIG 2-3-1. For runways having touchdown zone markings on both ends, those pairs of markings which extend to within 900 feet (270 m) of the midpoint between the thresholds are eliminated.

FIGURE 2-3-2

Nonprecision Instrument Runway and Visual Runway Markings

- f. **Runway Side Stripe Marking.** Runway side stripes delineate the edges of the runway. They provide a visual contrast between runway and the abutting terrain or shoulders. Side stripes consist of continuous white stripes located, on each side of the runway as shown in FIG 2-3-4.
- g. **Runway Shoulder Markings.** Runway shoulder stripes may be used to supplement runway side stripes to identify pavement areas contiguous to the runway sides that are not intended for use by aircraft. Runway shoulder stripes are yellow. (See FIG 2-3-5.)
- h. **Runway Threshold Markings.** Runway threshold markings come in two configurations. They either consist of eight longitudinal stripes of uniform dimensions disposed symmetrically about the runway centerline (as shown in FIG 2-3-1) or the number of stripes is related

US 2-3
SECTION 3. AIRPORT MARKING AIDS AND SIGNS

to the runway width as indicated in TBL 2-3-2. A threshold marking helps identify the beginning of the runway that is available for landing. In some instances, the landing threshold may be relocated or displaced.

TABLE 2-3-2 Number of Runway Threshold Stripes

Runway Width	Number of Stripes
60 feet (18 m)	4
75 feet (23 m)	6
100 feet (30 m)	8
150 feet (45 m)	12
200 feet (60 m)	16

1. **Relocation of a Threshold.** Sometimes construction, maintenance, or other activities require the threshold to be relocated towards the rollout end of the runway. (See FIG 2-3-3.) When a threshold is relocated, it closes not only a set portion of the approach end of a runway, but also shortens the length of the opposite direction runway. In these cases, a NOTAM should be issued by the airport operator identifying the portion of the runway that is closed (for example, 10/28 W 900 CLSD). Because the duration of the relocation can vary from a few hours to several months, methods identifying the new threshold may vary. One common practice is to use a ten feet wide white threshold bar across the width of the runway. Although the runway lights in the area between the old threshold and new threshold will not be illuminated, the runway markings in this area may or may not be obliterated, removed, or covered.
2. **Displaced Threshold.** A displaced threshold is a threshold located at a point on the runway other than the designated beginning of the runway. Displacement of a threshold reduces the length of runway available for landings. The portion of runway behind a displaced threshold is available for takeoffs in either direction and landings from the opposite direction. A ten feet wide white threshold bar is located across the width of the runway at the displaced threshold. White arrows are located along the centerline in the area between the beginning of the runway and displaced threshold. White arrow heads are located across the width of the runway just prior to the threshold bar, as shown in FIG 2-3-4.

NOTE: Airport operator. When reporting the relocation or displacement of a threshold, the airport operator should avoid language which confuses the two.

- i. **Demarcation Bar.** A demarcation bar delineates a runway with a displaced threshold from a blast pad, stopway, or taxiway that precedes the runway. A demarcation bar is 3 feet (1 m) wide and yellow, since it is not located on the runway, as shown in FIG 2-3-6.
 1. **Chevrons.** These markings are used to show pavement areas aligned with the runway that are unusable for landing, takeoff, and taxiing. Chevrons are yellow. (See FIG 2-3-7.)

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

- j. **Runway Threshold Bar.** A threshold bar delineates the beginning of the runway that is available for landing when the threshold has been relocated or displaced. A threshold bar is 10 feet (3m) in width and extends across the width of the runway, as shown in FIG 2-3-4.

FIGURE 2-3-3

Relocation of a Threshold with Markings for Taxiway Aligned with Runway

US 2-3
SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-4

Displaced Threshold Markings

US 2-3
SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-5

2-3-4 TAXIWAY MARKINGS

- a. **General.** All taxiways should have centerline markings and runway holding position markings whenever they intersect a runway. Taxiway edge markings are present whenever there is a need to separate the taxiway from a pavement that is not intended for aircraft use or to delineate the edge of the taxiway. Taxiways may also have shoulder markings and holding position markings for Instrument Landing System (ILS) critical areas and taxiway/taxiway intersection markings.

REFERENCE—AIM, Paragraph 2-3-5, *Holding Position Markings*.

- b. **Taxiway Centerline.**

1. **Normal Centerline.** The taxiway centerline is a single continuous yellow line, 6 inches (15 cm) to 12 inches (30 cm) in width. This provides a visual cue to permit taxiing along a designated path. Ideally, the aircraft should be kept centered over this line during taxi. However, being centered on the taxiway centerline does not guarantee wingtip clearance with other aircraft or other objects.

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

2. **Enhanced Centerline.** At some airports, mostly the larger commercial service airports, an enhanced taxiway centerline will be used. The enhanced taxiway centerline marking consists of a parallel line of yellow dashes on either side of the normal taxiway centerline. The taxiway centerlines are enhanced for a maximum of 150 feet prior to a runway holding position marking. The purpose of this enhancement is to warn the pilot that he/she is approaching a runway holding position marking and should prepare to stop unless he/she has been cleared onto or across the runway by ATC. (See FIG 2-3-8.)
- c. **Taxiway Edge Markings.** Taxiway edge markings are used to define the edge of the taxiway. They are primarily used when the taxiway edge does not correspond with the edge of the pavement. There are two types of markings depending upon whether the aircraft is supposed to cross the taxiway edge:
 1. **Continuous Markings.** These consist of a continuous double yellow line, with each line being at least 6 inches (15 cm) in width spaced 6 inches (15 cm) apart. They are used to define the taxiway edge from the shoulder or some other abutting paved surface not intended for use by aircraft.
 2. **Dashed Markings.** These markings are used when there is an operational need to define the edge of a taxiway or taxilane on a paved surface where the adjoining pavement to the taxiway edge is intended for use by aircraft (for example, an apron). Dashed taxiway edge markings consist of a broken double yellow line, with each line being at least 6 inches (15 cm) in width, spaced 6 inches (15 cm) apart (edge to edge). These lines are 15 feet (4.5 m) in length with 25 foot (7.5 m) gaps. (See FIG 2-3-9.)
- d. **Taxi Shoulder Markings.** Taxiways, holding bays, and aprons are sometimes provided with paved shoulders to prevent blast and water erosion. Although shoulders may have the appearance of full strength pavement, they are not intended for use by aircraft and may be unable to support an aircraft. Usually the taxiway edge marking will define this area. Where conditions exist such as islands or taxiway curves that may cause confusion as to which side of the edge stripe is for use by aircraft, taxiway shoulder markings may be used to indicate the pavement is unusable. Taxiway shoulder markings are yellow. (See FIG 2-3-10.)

FIGURE 2-3-8

Enhanced Taxiway Centerline

FIGURE 2-3-9

Dashed Markings

- e. **Surface Painted Taxiway Direction Signs.** Surface painted taxiway direction signs have a yellow background with a black inscription, and are provided when it is not possible to provide taxiway direction signs at intersections, or when necessary to supplement such signs. These markings are located adjacent to the centerline with signs indicating turns to the left

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

being on the left side of the taxiway centerline, and signs indicating turns to the right being on the right side of the centerline. (See FIG 2-3-11.)

FIGURE 2-3-10

Taxi Shoulder Markings

- f. **Surface Painted Location Signs.** Surface painted location signs have a black background with a yellow inscription. When necessary, these markings are used to supplement location signs located along side the taxiway and assist the pilot in confirming the designation of the taxiway on which the aircraft is located. These markings are located on the right side of the centerline. (See FIG 2-3-11.)
- g. **Geographic Position Markings.** These markings are located at points along low visibility taxi routes designated in the airport's Surface Movement Guidance Control System (SMGCS) plan. They are used to identify the location of taxiing aircraft during low visibility operations. Low visibility operations are those that occur when the runway visible range (RVR) is below 1200 feet (360 m). They are positioned to the left of the taxiway centerline in the direction of taxiing. (See FIG 2-3-12.) The geographic position marking is a circle comprised of an outer black ring contiguous to a white ring with a pink circle in the middle. When installed on asphalt or other dark-colored pavements, the white ring and the black ring are reversed (i.e., the white ring becomes the outer ring and the black ring becomes the inner ring). It is designated with either a number or a number and letter. The number corresponds to the consecutive position of the marking on the route.

US 2-3
SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-11
Surface Painted Signs

2-3-5 HOLDING POSITION MARKINGS

- a. **Runway Holding Position Markings.** For runways, these markings indicate where aircraft **MUST STOP** when approaching a runway. They consist of four yellow lines, two solid and two dashed, spaced six or twelve inches apart and extending across the width of the taxiway or runway. The solid lines are always on the side where the aircraft must hold. There are three locations where runway holding position markings are encountered.

1. **Runway Holding Position Markings on Taxiways.** These markings identify the locations on a taxiway where aircraft **MUST STOP** when a clearance has not been issued to proceed onto the runway. Generally, runway holding position markings also identify the boundary of the runway safety area (RSA) for aircraft exiting the runway. Runway holding position markings are shown in FIG 2-3-13 and FIG 2-3-16. When instructed by ATC, "Hold short of Runway XX," the pilot **MUST STOP** so that no part of the aircraft extends beyond the runway holding position marking. When approaching runways at airports with an operating control tower, pilots must not cross the runway holding position marking without ATC clearance. Pilots approaching runways at airports without an operating control tower must ensure adequate separation from other aircraft, vehicles, and pedestrians prior to crossing the holding position markings. An aircraft exiting a runway is not clear of the runway until all parts of the aircraft have crossed the applicable holding position marking.

NOTE: Runway holding position markings identify the beginning of an RSA, and a pilot **MUST STOP** to get clearance before crossing (at airports with operating control towers).

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

REFERENCE—AIM, Paragraph 4-3-20, *Exiting the Runway After Landing*.

2. Runway Holding Position Markings on Runways. These markings identify the locations on runways where aircraft **MUST STOP**. These markings are located on runways used by ATC for Land And Hold Short Operations (for example, see FIG 4-3-8) and Taxiing operations. For taxiing operations, the pilot **MUST STOP** prior to the holding position markings unless explicitly authorized to cross by ATC. A sign with a white inscription on a red background is located adjacent to these holding position markings. (See FIG 2-3-14.) The holding position markings are placed on runways prior to the intersection with another runway, or some designated point. Pilots receiving and accepting instructions “*Cleared to land Runway XX, hold short of Runway YY*” from ATC must either exit Runway XX prior to the holding position markings, or stop at the holding position markings prior to Runway YY. Otherwise, pilots are authorized to use the entire landing length of the runway and disregard the holding position markings.

3. Holding Position Markings on Taxiways Located in Runway Approach Areas. These markings are used at some airports where it is necessary to hold an aircraft on a taxiway located in the approach or departure area of a runway so that the aircraft does not interfere with the operations on that runway. This marking is collocated with the runway approach/departure area holding position sign. When specifically instructed by ATC, “*Hold short of Runway XX approach or Runway XX departure area,*” the pilot **MUST STOP** so that no part of the aircraft extends beyond the holding position marking. (See Subparagraph 2-3-8b2, Runway Approach Area Holding Position Sign, and FIG 2-3-15.)

b. Holding Position Markings for Instrument Landing System (ILS). Holding position markings for ILS critical areas consist of two yellow solid lines spaced two feet apart connected by pairs of solid lines spaced ten feet apart extending across the width of the taxiway as shown. (See FIG 2-3-16.) A sign with an inscription in white on a red background is located adjacent to these hold position markings. When instructed by ATC to hold short of the ILS critical area, pilots **MUST STOP** so that no part of the aircraft extends beyond the holding position marking. When approaching the holding position marking, pilots must not cross the marking without ATC clearance. The ILS critical area is not clear until all parts of the aircraft have crossed the applicable holding position marking.

REFERENCE—AIM, Paragraph 1-1-9, *Instrument Landing System (ILS)*.

c. Holding Position Markings for Intersecting Taxiways. Holding position markings for intersecting taxiways consist of a single dashed line extending across the width of the taxiway as shown. (See FIG 2-3-17.) They are located on taxiways where ATC holds aircraft short of a taxiway intersection. When instructed by ATC, “*Hold short of Taxiway XX,*” the pilot **MUST STOP** so that no part of the aircraft extends beyond the holding position marking. When the marking is not present, the pilot **MUST STOP** the aircraft at a point which provides adequate clearance from an aircraft on the intersecting taxiway.

d. Surface Painted Holding Position Signs. Surface painted holding position signs have a red background with a white inscription and supplement the signs located at the holding

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

position. This type of marking is normally used where the width of the holding position on the taxiway is greater than 200 feet (60 m). It is located to the left side of the taxiway centerline on the holding side and prior to the holding position marking. (See FIG 2-3-11.)

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-16

Holding Position Markings: ILS Critical Area

2-3-6 OTHER MARKINGS

- a. **Vehicle Roadway Markings.** The vehicle roadway markings are used when necessary to define a pathway for vehicle operations on or crossing areas that are also intended for aircraft. These markings consist of a white solid line to delineate each edge of the roadway and a dashed line to separate lanes within the edges of the roadway. In lieu of the solid lines, zipper markings may be used to delineate the edges of the vehicle roadway. (See FIG 2-3-18.) Details of the zipper markings are shown in FIG 2-3-19.
- b. **VOR Receiver Checkpoint Markings.** The VOR receiver checkpoint marking allows the pilot to check aircraft instruments with navigational aid signals. It consists of a painted circle with an arrow in the middle; the arrow is aligned in the direction of the checkpoint azimuth. This marking, and an associated sign, is located on the airport apron or taxiway at a point selected for easy access by aircraft but where other airport traffic is not to be unduly obstructed. (See FIG 2-3-20.)

NOTE: The associated sign contains the VOR station identification letter and course selected (published) for the check, the words "VOR check course," and DME data (when applicable). The color of the letters and numerals are black on a yellow background.

EXAMPLE: DCA 176-356

US 2-3
SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-19

Roadway Edge Stripes, White, Zipper Style

- c. **Nonmovement Area Boundary Markings.** These markings delineate the movement area (i.e., area under ATC). These markings are yellow and located on the boundary between the movement and nonmovement area. The nonmovement area boundary markings consist of two yellow lines (one solid and one dashed) 6 inches (15 cm) in width. The solid line is located on the nonmovement area side, while the dashed yellow line is located on the movement area side. The nonmovement boundary marking area is shown in FIG 2-3-21.

FIGURE 2-3-21

FIGURE 2-3-22

Closed or Temporarily Closed Runway and Taxiway Markings

- d. **Marking and Lighting of Permanently Closed Runways and Taxiways.** For runways and taxiways which are permanently closed, the lighting circuits will be disconnected. The runway threshold, runway designation, and touchdown markings are obliterated and yellow crosses are placed at each end of the runway and at 1,000 foot intervals. (See FIG 2-3-22.)

FIGURE 2-3-23

Helicopter Landing Areas

- e. **Temporarily Closed Runways and Taxiways.** To provide a visual indication to pilots that a runway is temporarily closed, crosses are placed on the runway only at each end of the runway. The crosses are yellow in color. (See FIG 2-3-22.)

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

1. A raised lighted yellow cross may be placed on each runway end in lieu of the markings described in Subparagraph e, Temporarily Closed Runways and Taxiways, to indicate the runway is closed.
 2. A visual indication may not be present depending on the reason for the closure, duration of the closure, airfield configuration, and the existence and the hours of operation of an airport traffic control tower. Pilots should check NOTAMs and the Automated Terminal Information System (ATIS) for local runway and taxiway closure information.
 3. Temporarily closed taxiways are usually treated as hazardous areas, in which no part of an aircraft may enter, and are blocked with barricades. However, as an alternative, a yellow cross may be installed at each entrance to the taxiway.
- f. **Helicopter Landing Areas.** The markings illustrated in FIG 2-3-23 are used to identify the landing and takeoff area at a public use heliport and hospital heliport. The letter “H” in the markings is oriented to align with the intended direction of approach. FIG 2-3-23 also depicts the markings for a closed airport.

2-3-7 AIRPORT SIGNS

There are six types of signs installed on airfields: mandatory instruction signs, location signs, direction signs, destination signs, information signs, and runway distance remaining signs. The characteristics and use of these signs are discussed in Paragraph 2-3-8, Mandatory Instruction Signs, through Paragraph 2-3-13, Runway Distance Remaining Signs. [See Jeppesen Introduction pages 151 through 157.]

REFERENCE—AC150/5340-18, *Standards for Airport Sign Systems for Detailed Information on Airport Signs*.

FIGURE 2-3-24

Runway Holding Position Sign

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-25

Holding Position Sign at Beginning of Takeoff Runway

2-3-8 MANDATORY INSTRUCTION SIGNS

a. These signs have a red background with a white inscription and are used to denote:

1. An entrance to a runway or critical area; and
2. Areas where an aircraft is prohibited from entering.

b. **Typical mandatory signs and applications are:**

1. **Runway Holding Position Sign.** This sign is located at the holding position on taxiways that intersect a runway or on runways that intersect other runways. The inscription on the sign contains the designation of the intersecting runway, as shown in FIG 2-3-24. The runway numbers on the sign are arranged to correspond to the respective runway threshold. For example, "15-33" indicates that the threshold for Runway 15 is to the left and the threshold for Runway 33 is to the right.

- (a) On taxiways that intersect the beginning of the takeoff runway, only the designation of the takeoff runway may appear on the sign (as shown in FIG 2-3-25), while all other signs will have the designation of both runway directions.

FIGURE 2-3-26

Holding Position Sign for a Taxiway that Intersects the Intersection of Two Runways

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-27

Holding Position Sign for a Runway Approach Area

- (b) If the sign is located on a taxiway that intersects the intersection of two runways, the designations for both runways will be shown on the sign along with arrows showing the approximate alignment of each runway, as shown in FIG 2-3-26. In addition to showing the approximate runway alignment, the arrow indicates the direction to the threshold of the runway whose designation is immediately next to the arrow.
- (c) A runway holding position sign on a taxiway will be installed adjacent to holding position markings on the taxiway pavement. On runways, holding position markings will be located only on the runway pavement adjacent to the sign, if the runway is normally used by ATC for “Land, Hold Short” operations or as a taxiway. The holding position markings are described in Paragraph 2-3-5, Holding Position Markings.
2. **Runway Approach Area Holding Position Sign.** At some airports, it is necessary to hold an aircraft on a taxiway located in the approach or departure area for a runway so that the aircraft does not interfere with operations on that runway. In these situations, a sign with the designation of the approach end of the runway followed by a “dash” (-) and letters “APCH” will be located at the holding position on the taxiway. Holding position markings in accordance with Paragraph 2-3-5, Holding Position Markings, will be located on the taxiway pavement. An example of this sign is shown in FIG 2-3-27. In this example, the sign may protect the approach to Runway 15 and/or the departure for Runway 33.

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-28

Holding Position Sign for ILS Critical Area

FIGURE 2-3-29

Sign Prohibiting Aircraft Entry into an Area

3. **ILS Critical Area Holding Position Sign.** At some airports, when the instrument landing system is being used, it is necessary to hold an aircraft on a taxiway at a location other than the holding position described in Paragraph 2-3-5, Holding Position Markings. In these situations, the holding position sign for these operations will have the inscription "ILS" and be located adjacent to the holding position marking on the taxiway described in paragraph 2-3-5. An example of this sign is shown in FIG 2-3-28.
4. **No Entry Sign.** This sign, shown in FIG 2-3-29, prohibits an aircraft from entering an area. Typically, this sign would be located on a taxiway intended to be used in only one direction or at the intersection of vehicle roadways with runways, taxiways, or aprons where the roadway may be mistaken as a taxiway or other aircraft movement surface.

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

NOTE: Holding position signs provide the pilot with a visual cue as to the location of the holding position marking.

REFERENCE—AIM Paragraph 2-3-5, Holding Position Markings.

FIGURE 2-3-30

Taxiway Location Sign

**FIGURE 2-3-31**

Taxiway Location Sign Collocated with Runway Holding Position Sign

**2-3-9 LOCATION SIGNS**

- a. Location signs are used to identify either a taxiway or runway on which the aircraft is located. Other location signs provide a visual cue to pilots to assist them in determining when they have exited an area. The various location signs are described below.

1. **Taxiway Location Sign.** This sign has a black background with a yellow inscription and yellow border, as shown in FIG 2-3-30. The inscription is the designation of the taxiway on which the aircraft is located. These signs are installed along taxiways either by themselves or in conjunction with direction signs or runway holding position signs. (See FIG 2-3-35 and FIG 2-3-31.)

US 2-3
SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-32

Runway Location Sign

FIGURE 2-3-33

Runway Boundary Sign

2. **Runway Location Sign.** This sign has a black background with a yellow inscription and yellow border, as shown in FIG 2-3-32. The inscription is the designation of the runway on which the aircraft is located. These signs are intended to complement the information available to pilots through their magnetic compass and typically are installed where the proximity of two or more runways to one another could cause pilots to be confused as to which runway they are on.
3. **Runway Boundary Sign.** This sign has a yellow background with a black inscription with a graphic depicting the pavement holding position marking, as shown in FIG 2-3-33. This sign, which faces the runway and is visible to the pilot exiting the runway, is located adjacent to the holding position marking on the pavement. The sign is intended to provide pilots with another visual cue which they can use as a guide in deciding when they are “clear of the runway.”

US 2-3
SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-34

ILS Critical Area Boundary Sign

4. **ILS Critical Area Boundary Sign.** This sign has a yellow background with a black inscription with a graphic depicting the ILS pavement holding position marking as shown in FIG 2-3-34. This sign is located adjacent to the ILS holding position marking on the pavement and can be seen by pilots leaving the critical area. The sign is intended to provide pilots with another visual cue which they can use as a guide in deciding when they are “clear of the ILS critical area.”

2-3-10 DIRECTION SIGNS

- a. Direction signs have a yellow background with a black inscription. The inscription identifies the designation(s) of the intersecting taxiway(s) leading out of the intersection that a pilot would normally be expected to turn onto or hold short of. Each designation is accompanied by an arrow indicating the direction of the turn.
- b. Except as noted in subparagraph e, each taxiway designation shown on the sign is accompanied by only one arrow. When more than one taxiway designation is shown on the sign, each designation and its associated arrow is separated from the other taxiway designations by either a vertical message divider or a taxiway location sign as shown in FIG 2-3-35.
- c. Direction signs are normally located on the left prior to the intersection. When used on a runway to indicate an exit, the sign is located on the same side of the runway as the exit. FIG 2-3-36 shows a direction sign used to indicate a runway exit.
- d. The taxiway designations and their associated arrows on the sign are arranged clockwise starting from the first taxiway on the pilot's left. (See FIG 2-3-35.)
- e. If a location sign is located with the direction signs, it is placed so that the designations for all turns to the left will be to the left of the location sign; the designations for continuing straight ahead or for all turns to the right would be located to the right of the location sign. (See FIG 2-3-35.)
- f. When the intersection is comprised of only one crossing taxiway, it is permissible to have two arrows associated with the crossing taxiway, as shown in FIG 2-3-37. In this case, the location sign is located to the left of the direction sign.

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIGURE 2-3-38

Destination Sign for Military Area

FIGURE 2-3-39

Destination Sign for Common Taxiing Route to Two Runways

2-3-11 DESTINATION SIGNS

- a. Destination signs also have a yellow background with a black inscription indicating a destination on the airport. These signs always have an arrow showing the direction of the taxiing

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

route to that destination. FIG 2-3-38 is an example of a typical destination sign. When the arrow on the destination sign indicates a turn, the sign is located prior to the intersection.

- b. Destinations commonly shown on these types of signs include runways, aprons, terminals, military areas, civil aviation areas, cargo areas, international areas, and fixed base operators. An abbreviation may be used as the inscription on the sign for some of these destinations.
- c. When the inscription for two or more destinations having a common taxiing route are placed on a sign, the destinations are separated by a “dot” (•) and one arrow would be used, as shown in FIG 2-3-39. When the inscription on a sign contains two or more destinations having different taxiing routes, each destination will be accompanied by an arrow and will be separated from the other destinations on the sign with a vertical black message divider, as shown in FIG 2-3-40.

FIGURE 2-3-40

Destination Sign for Different Taxiing Routes to Two Runways

2-3-12 INFORMATION SIGNS

Information signs have a yellow background with a black inscription. They are used to provide the pilot with information on such things as areas that cannot be seen from the control tower, applicable radio frequencies, and noise abatement procedures. The airport operator determines the need, size, and location for these signs.

2-3-13 RUNWAY DISTANCE REMAINING SIGNS

Runway distance remaining signs have a black background with a white numeral inscription and may be installed along one or both side(s) of the runway. The number on the signs indicates the distance (in thousands of feet) of landing runway remaining. The last sign (i.e., the sign with the numeral “1”) will be located at least 950 feet from the runway end. FIG 2-3-41 shows an example of a runway distance remaining sign.

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIG 2-3-41

Runway Distance Remaining Sign Indicating 3,000 feet of Runway Remaining

2-3-14 AIRCRAFT ARRESTING SYSTEMS

- a. Certain airports are equipped with a means of rapidly stopping military aircraft on a runway. This equipment, normally referred to as EMERGENCY ARRESTING GEAR, generally consists of pendant cables supported over the runway surface by rubber “donuts.” Although most devices are located in the overrun areas, a few of these arresting systems have cables stretched over the operational areas near the ends of a runway.
- b. Arresting cables which cross over a runway require special markings on the runway to identify the cable location. These markings consist of 10 feet diameter solid circles painted “identification yellow,” 30 feet on center, perpendicular to the runway centerline across the entire runway width. Additional details are contained in AC 150/5220-9, Aircraft Arresting Systems for Joint Civil/Military Airports.

NOTE: Aircraft operations on the runway are not restricted by the installation of aircraft arresting devices.

- c. **Engineered Materials Arresting Systems (EMAS).** EMAS, which is constructed of high energy-absorbing materials of selected strength, is located in the safety area beyond the end of the runway. EMAS will be marked with yellow chevrons. EMAS is designed to crush under the weight of commercial aircraft and will exert deceleration forces on the landing gear. These systems do not affect the normal landing and takeoff of airplanes. More information concerning EMAS is in AC 150/5220-22, Engineered Materials Arresting Systems (EMAS) for Aircraft Overruns.

NOTE: EMAS may be located as close as 35 feet beyond the end of the runway. Aircraft and ground vehicles should never taxi or drive across the EMAS or beyond the end of the runway if EMAS is present.

US 2-3

SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIG 2-3-42

Engineered Materials Arresting System (EMAS)

**2-3-15 SECURITY IDENTIFICATION DISPLAY AREA (SIDA)**

- a. Security Identification Display Areas (SIDA) are limited access areas that require a badge issued in accordance with procedures in 49 CFR Part 1542. A SIDA can include the Air Operations Area (AOA), e.g., aircraft movement area or parking area, or a Secured Area, such as where commercial passengers enplane. The AOA may not be a SIDA, but a Secured Area is always a SIDA. Movement through or into a SIDA is prohibited without authorization and proper identification being displayed. If you are unsure of the location of a SIDA, contact the airport authority for additional information. Airports that have a SIDA will have a description and map detailing boundaries and pertinent features available.
- b. Pilots or passengers without proper identification that are observed entering a SIDA may be reported to the Transportation Security Administration (TSA) or airport security and may be subject to civil and criminal fines and prosecution. Pilots are advised to brief passengers accordingly. Report suspicious activity to the TSA by calling AOPA's Airport Watch Program, 866-427-3287. 49 CFR 1540 requires each individual who holds an airman certificate, medical certificate, authorization, or license issued by the FAA to present it for inspection upon a request from TSA.

US 2-3
SECTION 3. AIRPORT MARKING AIDS AND SIGNS

FIG 2-3-43

Sample SIDA Warning Sign

US 3-1
SECTION 1. GENERAL**3-1-1 GENERAL**

- a. There are two categories of airspace or airspace areas:
 1. Regulatory (Class A, B, C, D and E airspace areas, restricted and prohibited areas); and
 2. Nonregulatory (military operations areas [MOA], warning areas, alert areas, controlled firing areas [CFA], and national security areas [NSA]).

NOTE: *Additional information on special use airspace (prohibited areas, restricted areas [permanent or temporary], warning areas, MOAs [permanent or temporary], alert areas, CFAs, and NSAs) may be found in Chapter 3, Airspace, Section 4, Special Use Airspace, paragraphs 3-4-1 through 3-4-8.*
- b. Within these two categories, there are four types:
 1. Controlled;
 2. Uncontrolled;
 3. Special use; and
 4. Other airspace.
- c. The categories and types of airspace are dictated by:
 1. The complexity or density of aircraft movements,
 2. The nature of the operations conducted within the airspace,
 3. The level of safety required, and
 4. The national and public interest.
- d. It is important that pilots be familiar with the operational requirements for each of the various types or classes of airspace. Subsequent sections will cover each class in sufficient detail to facilitate understanding.

3-1-2 GENERAL DIMENSIONS OF AIRSPACE SEGMENTS

Refer to Title 14 of the U.S. Code of Federal Regulations (CFR) for specific dimensions, exceptions, geographical areas covered, exclusions, specific transponder/ADS-B or other equipment requirements, and flight operations.

3-1-3 HIERARCHY OF OVERLAPPING AIRSPACE DESIGNATIONS

- a. When overlapping airspace designations apply to the same airspace, the operating rules associated with the more restrictive airspace designation apply.
- b. For the purpose of clarification:
 1. Class A airspace is more restrictive than Class B, Class C, Class D, Class E, or Class G airspace;

US 3-1
SECTION 1. GENERAL

2. Class B airspace is more restrictive than Class C, Class D, Class E, or Class G airspace;
3. Class C airspace is more restrictive than Class D, Class E, or Class G airspace;
4. Class D airspace is more restrictive than Class E or Class G airspace; and
5. Class E is more restrictive than Class G airspace.

3-1-4 BASIC VFR WEATHER MINIMUMS

- a. No person may operate an aircraft under basic VFR when the flight visibility is less, or at a distance from clouds that is less, than that prescribed for the corresponding altitude and class of airspace. (See TBL 3-1-1.)

NOTE: *Student pilots must comply with 14 CFR Section 61.89(a) (6) and (7).*

- b. Except as provided in 14 CFR Section 91.157, Special VFR Weather Minimums, no person may operate an aircraft beneath the ceiling under VFR within the lateral boundaries of controlled airspace designated to the surface for an airport when the ceiling is less than 1,000 feet. (See 14 CFR Section 91.155(c).)

TABLE 3-1-1 Basic VFR Weather Minimums

Airspace	Flight Visibility	Distance from Clouds
Class A	Not Applicable	Not Applicable
Class B	3 statute miles	Clear of Clouds
Class C	3 statute miles	500 feet below 1,000 feet above 2,000 feet horizontal
Class D	3 statute miles	500 feet below 1,000 feet above 2,000 feet horizontal
Class E Less than 10,000 feet MSL	3 statute miles	500 feet below 1,000 feet above 2,000 feet horizontal
At or above 10,000 feet MSL	5 statute miles	1,000 feet below 1,000 feet above 1 statute mile horizontal
Class G 1,200 feet or less above the surface (regardless of MSL altitude).		

**US 3-1
SECTION 1. GENERAL**

TABLE 3-1-1 Basic VFR Weather Minimums (continued)

Airspace	Flight Visibility	Distance from Clouds
For aircraft other than helicopters:		
Day, except as provided in §91.155(b)	1 statute mile	Clear of clouds
Night, except as provided in §91.155(b)	3 statute miles	500 feet below 1,000 feet above 2,000 feet horizontal
For helicopters:		
Day	½ statute mile	Clear of clouds
Night, except as provided in §91.155(b)	1 statute mile	Clear of clouds
More than 1,200 feet above the surface but less than 10,000 feet MSL.		
Day	1 statute mile	500 feet below 1,000 feet above 2,000 feet horizontal
Night	3 statute miles	500 feet below 1,000 feet above 2,000 feet horizontal
More than 1,200 feet above the surface and at or above 10,000 feet MSL.	5 statute miles	1,000 feet below 1,000 feet above 1 statute mile horizontal

3-1-5 VFR CRUISING ALTITUDES AND FLIGHT LEVELS

(See TBL 3-1-2.)

TABLE 3-1-2 VFR Cruising Altitudes and Flight Levels

If your magnetic course (ground track) is:	And you are more than 3,000 feet above the surface but below 18,000 feet MSL, fly:	And you are above 18,000 feet MSL to FL 290, fly:
0° to 179°	Odd thousands MSL, plus 500 feet (3,500; 5,500; 7,500, etc.)	Odd Flight Levels plus 500 feet (FL 195; FL 215; FL 235, etc.)
180° to 359°	Even thousands MSL, plus 500 feet (4,500; 6,500; 8,500, etc.)	Even Flight Levels plus 500 feet (FL 185; FL 205; FL 225, etc.)

US 3-2

SECTION 2. CONTROLLED AIRSPACE

3-2-1 GENERAL

- a. **Controlled Airspace.** A generic term that covers the different classification of airspace (Class A, Class B, Class C, Class D, and Class E airspace) and defined dimensions within which air traffic control service is provided to IFR flights and to VFR flights in accordance with the airspace classification. (See FIG 3-2-1.)
- b. **IFR Requirements.** IFR operations in any class of controlled airspace requires that a pilot must file an IFR flight plan and receive an appropriate ATC clearance.
- c. **IFR Separation.** Standard IFR separation is provided to all aircraft operating under IFR in controlled airspace.
- d. **VFR Requirements.** It is the responsibility of the pilot to ensure that ATC clearance or radio communication requirements are met prior to entry into Class B, Class C, or Class D airspace. The pilot retains this responsibility when receiving ATC radar advisories. (See 14 CFR Part 91.)
- e. **Traffic Advisories.** Traffic advisories will be provided to all aircraft as the controller's work situation permits.
- f. **Safety Alerts.** Safety Alerts are mandatory services and are provided to ALL aircraft. There are two types of Safety Alerts:
 - 1. **Terrain/Obstruction Alert.** A Terrain/Obstruction Alert is issued when, in the controller's judgment, an aircraft's altitude places it in unsafe proximity to terrain and/or obstructions; and
 - 2. **Aircraft Conflict/Mode C Intruder Alert.** An Aircraft Conflict/Mode C Intruder Alert is issued if the controller observes another aircraft which places it in an unsafe proximity. When feasible, the controller will offer the pilot an alternative course of action.

US 3-2
SECTION 2. CONTROLLED AIRSPACEFIGURE 3-2-1
Airspace Classes

- g. **Ultralight Vehicles.** No person may operate an ultralight vehicle within Class A, Class B, Class C, or Class D airspace or within the lateral boundaries of the surface area of Class E airspace designated for an airport unless that person has prior authorization from the ATC facility having jurisdiction over that airspace. (See 14 CFR Part 103.)
- h. **Unmanned Free Balloons.** Unless otherwise authorized by ATC, no person may operate an unmanned free balloon below 2,000 feet above the surface within the lateral boundaries of Class B, Class C, Class D, or Class E airspace designated for an airport. (See 14 CFR Part 101.)
- i. **Parachute Jumps.** No person may make a parachute jump, and no pilot-in-command may allow a parachute jump to be made from that aircraft, in or into Class A, Class B, Class C, or Class D airspace without, or in violation of, the terms of an ATC authorization issued by the ATC facility having jurisdiction over the airspace. (See 14 CFR Part 105.)

3-2-2 CLASS A AIRSPACE

- a. **Definition.** Generally, that airspace from 18,000 feet MSL up to and including FL 600, including the airspace overlying the waters within 12 nautical miles off the coast of the 48 contiguous States and Alaska; and designated international airspace beyond 12 nautical miles off the coast of the 48 contiguous States and Alaska within areas of domestic radio navigational signal or ATC radar coverage, and within which domestic procedures are applied.

US 3-2

SECTION 2. CONTROLLED AIRSPACE

- b. **Operating Rules and Pilot/Equipment Requirements.** Unless otherwise authorized, all persons must operate their aircraft under IFR. (See 14 CFR Section 71.33, Sections 91.167 through 91.193, Sections 91.215 through 91.217, and Sections 91.225 through 91.227.)
- c. **Charts.** Class A airspace is not specifically charted.

3-2-3 CLASS B AIRSPACE

- a. **Definition.** Generally, that airspace from the surface to 10,000 feet MSL surrounding the nation's busiest airports in terms of IFR operations or passenger enplanements. The configuration of each Class B airspace area is individually tailored and consists of a surface area and two or more layers (some Class B airspace areas resemble upside-down wedding cakes), and is designed to contain all published instrument procedures once an aircraft enters the airspace. An ATC clearance is required for all aircraft to operate in the area, and all aircraft that are so cleared receive separation services within the airspace. The cloud clearance requirement for VFR operations is "clear of clouds."
- b. **Operating Rules and Pilot/Equipment Requirements.** Regardless of weather conditions, an ATC clearance is required prior to operating within Class B airspace. Pilots should not request a clearance to operate within Class B airspace unless the requirements of 14 CFR Sections 91.131, 91.215, and 91.225 are met. Included among these requirements are:
 - 1. Unless otherwise authorized by ATC, aircraft must be equipped with an operable two-way radio capable of communicating with ATC on appropriate frequencies for that Class B airspace.
 - 2. No person may take off or land a civil aircraft at the following primary airports within Class B airspace unless the pilot-in-command holds at least a private pilot certificate:
 - (a) Andrews Air Force Base, MD
 - (b) Atlanta Hartsfield Airport, GA
 - (c) Boston Logan Airport, MA
 - (d) Chicago O'Hare Intl. Airport, IL
 - (e) Dallas/Fort Worth Intl. Airport, TX
 - (f) Los Angeles Intl. Airport, CA
 - (g) Miami Intl. Airport, FL
 - (h) Newark Intl. Airport, NJ
 - (i) New York Kennedy Airport, NY
 - (j) New York La Guardia Airport, NY
 - (k) Ronald Reagan Washington National Airport, DC
 - (l) San Francisco Intl. Airport, CA
 - 3. No person may take off or land a civil aircraft at an airport within Class B airspace or operate a civil aircraft within Class B airspace unless:

US 3-2

SECTION 2. CONTROLLED AIRSPACE

- (a) The pilot-in-command holds at least a private pilot certificate; or
 - (b) The pilot-in-command holds a recreational pilot certificate and has met the requirements of 14 CFR Section 61.101; or
 - (c) The pilot-in-command holds a sport pilot certificate and has met the requirements of 14 CFR Section 61.325; or
 - (d) The aircraft is operated by a student pilot:
 - (1) Who seeks a private pilot certificate and has met the requirements of 14 CFR Section 61.95.
 - (2) Who seeks a recreational pilot or sport pilot certificate and has met the requirements of 14 CFR Section 61.94.
4. Unless otherwise authorized by ATC, each person operating a large turbine engine-powered airplane to or from a primary airport must operate at or above the designated floors while within the lateral limits of Class B airspace.
5. Unless otherwise authorized by ATC, each aircraft must be equipped as follows:
- (a) For IFR operations, an operable VOR or TACAN receiver or an operable and suitable RNAV system; and
 - (b) For all operations, a two-way radio capable of communications with ATC on appropriate frequencies for that area; and
 - (c) Unless otherwise authorized by ATC, an operable radar beacon transponder with automatic altitude reporting capability and operable ADS-B Out equipment.

NOTE: *ATC may, upon notification, immediately authorize a deviation from the altitude reporting equipment requirement; however, a request for a deviation from the 4096 transponder equipment requirement must be submitted to the controlling ATC facility at least one hour before the proposed operation. A request for a deviation from the ADS-B equipage requirement must be submitted using the FAA's automated web authorization tool at least one hour but not more than 24 hours before the proposed operation.*

REFERENCE—AIM, Paragraph 4-1-20, *Transponder and ADS-B Out Operation AC 90-114, Automatic Dependent Surveillance-Broadcast Operations.*

6. **Mode C Veil.** The airspace within 30 nautical miles of an airport listed in Appendix D, Section 1 of 14 CFR Part 91 (generally primary airports within Class B airspace areas), from the surface upward to 10,000 feet MSL. Unless otherwise authorized by ATC, aircraft operating within this airspace must be equipped with an operable radar beacon transponder with automatic altitude reporting capability and operable ADS-B Out equipment.

However, aircraft that were not originally certificated with an engine-driven electrical system or that have not subsequently been certified with a system installed may conduct operations within a Mode C veil provided the aircraft remains outside Class A, B or

US 3-2

SECTION 2. CONTROLLED AIRSPACE

C airspace; and below the altitude of the ceiling of a Class B or Class C airspace area designated for an airport or 10,000 feet MSL, whichever is lower.

c. **Charts.** Class B airspace is charted on Sectional Charts, IFR En Route Low Altitude, and Terminal Area Charts. [See also Jeppesen Low Altitude Enroute Charts, Area Charts, and Class B Charts.]

d. **Flight Procedures.**

1. **Flights.** Aircraft within Class B airspace are required to operate in accordance with current IFR procedures. A clearance for a visual approach to a primary airport is not authorization for turbine-powered airplanes to operate below the designated floors of the Class B airspace.

2. **VFR Flights.**

(a) Arriving aircraft must obtain an ATC clearance prior to entering Class B airspace and must contact ATC on the appropriate frequency, and in relation to geographical fixes shown on local charts. Although a pilot may be operating beneath the floor of the Class B airspace on initial contact, communications with ATC should be established in relation to the points indicated for spacing and sequencing purposes.

(b) Departing aircraft require a clearance to depart Class B airspace and should advise the clearance delivery position of their intended altitude and route of flight. ATC will normally advise VFR aircraft when leaving the geographical limits of the Class B airspace. Radar service is not automatically terminated with this advisory unless specifically stated by the controller.

(c) Aircraft not landing or departing the primary airport may obtain an ATC clearance to transit the Class B airspace when traffic conditions permit and provided the requirements of 14 CFR Section 91.131 are met. Such VFR aircraft are encouraged, to the extent possible, to operate at altitudes above or below the Class B airspace or transit through established VFR corridors. Pilots operating in VFR corridors are urged to use frequency 122.750 MHz for the exchange of aircraft position information.

e. **ATC Clearances and Separation.** An ATC clearance is required to enter and operate within Class B airspace. VFR pilots are provided sequencing and separation from other aircraft while operating within Class B airspace.

REFERENCE—AIM, Paragraph 4-1-18, Terminal Radar Services for VFR Aircraft.

NOTE: Separation and sequencing of VFR aircraft will be suspended in the event of a radar outage as this service is dependent on radar. The pilot will be advised that the service is not available and issued wind, runway information and the time or place to contact the tower.

1. VFR aircraft are separated from all VFR/IFR aircraft which weigh 19,000 pounds or less by a minimum of:

(a) Target resolution, or

US 3-2

SECTION 2. CONTROLLED AIRSPACE

- (b) 500 feet vertical separation, or
 - (c) Visual separation.
2. VFR aircraft are separated from all VFR/IFR aircraft which weigh more than 19,000 and turbojets by no less than:
- (a) 1 $\frac{1}{2}$ miles lateral separation, or
 - (b) 500 feet vertical separation, or
 - (c) Visual separation.
3. This program is not to be interpreted as relieving pilots of their responsibilities to see and avoid other traffic operating in basic VFR weather conditions, to adjust their operations and flight path as necessary to preclude serious wake encounters, to maintain appropriate terrain and obstruction clearance or to remain in weather conditions equal to or better than the minimums required by 14 CFR Section 91.155. Approach control should be advised and a revised clearance or instruction obtained when compliance with an assigned route, heading and/or altitude is likely to compromise pilot responsibility with respect to terrain and obstruction clearance, vortex exposure, and weather minimums.
4. ATC may assign altitudes to VFR aircraft that do not conform to 14 CFR Section 91.159. **“RESUME APPROPRIATE VFR ALTITUDES”** will be broadcast when the altitude assignment is no longer needed for separation or when leaving Class B airspace. Pilots must return to an altitude that conforms to 14 CFR Section 91.159.
- f. **Proximity operations.** VFR aircraft operating in proximity to Class B airspace are cautioned against operating too closely to the boundaries, especially where the floor of the Class B airspace is 3,000 feet or less above the surface or where VFR cruise altitudes are at or near the floor of higher levels. Observance of this precaution will reduce the potential for encountering an aircraft operating at the altitudes of Class B floors. Additionally, VFR aircraft are encouraged to utilize the VFR Planning Chart as a tool for planning flight in proximity to Class B airspace. Charted VFR Flyway Planning Charts are published on the back of the existing VFR Terminal Area Charts.

3-2-4 CLASS C AIRSPACE

- a. **Definition.** Generally, that airspace from the surface to 4,000 feet above the airport elevation (charted in MSL) surrounding those airports that have an operational control tower, are serviced by a radar approach control, and that have a certain number of IFR operations or passenger enplanements. Although the configuration of each Class C airspace area is individually tailored, the airspace usually consists of a 5 NM radius core surface area that extends from the surface up to 4,000 feet above the airport elevation, and a 10 NM radius shelf area that extends no lower than 1,200 feet up to 4,000 feet above the airport elevation.
- b. **Charts.** Class C airspace is charted on Sectional Charts, IFR En Route Low Altitude, and Terminal Area Charts where appropriate.

US 3-2

SECTION 2. CONTROLLED AIRSPACE

c. **Operating Rules and Pilot/Equipment Requirements:**

1. **Pilot Certification.** No specific certification required.

2. **Equipment.**

(a) Two-way radio; and

(b) Unless otherwise authorized by ATC, an operable radar beacon transponder with automatic altitude reporting capability and operable ADS-B Out equipment.

NOTE: See Paragraph 4-1-20, *Transponder and ADS-B Out Operation*, subparagraph f for Mode C transponder/ADS-B requirements for operating above Class C airspace.

3. **Arrival or Through Flight Entry Requirements.** Two-way radio communication must be established with the ATC facility providing ATC services prior to entry and thereafter maintain those communications while in Class C airspace. Pilots of arriving aircraft should contact the Class C airspace ATC facility on the publicized frequency and give their position, altitude, radar beacon code, destination, and request Class C service. Radio contact should be initiated far enough from the Class C airspace boundary to preclude entering Class C airspace before two-way radio communications are established.

NOTE:

1. *If the controller responds to a radio call with, “(aircraft callsign) standby,” radio communications have been established and the pilot can enter the Class C airspace.*
2. *If workload or traffic conditions prevent immediate provision of Class C services, the controller will inform the pilot to remain outside the Class C airspace until conditions permit the services to be provided.*
3. *It is important to understand that if the controller responds to the initial radio call without using the aircraft identification, radio communications have not been established and the pilot may not enter the Class C airspace.*
4. *Class C airspace areas have a procedural Outer Area. Normally this area is 20 NM from the primary Class C airspace airport. Its vertical limit extends from the lower limits of radio/radar coverage up to the ceiling of the approach control’s delegated airspace, excluding the Class C airspace itself, and other airspace as appropriate. (This outer area is not charted.)*
5. *Pilots approaching an airport with Class C service should be aware that if they descend below the base altitude of the 5 to 10 mile shelf during an instrument or visual approach, they may encounter non-transponder/non-ADS-B VFR aircraft.*

EXAMPLE:

1. [Aircraft callsign] “remain outside the Class Charlie airspace and standby.”
2. “Aircraft calling Dulles approach control, standby.”

US 3-2

SECTION 2. CONTROLLED AIRSPACE

4. **Departures from:**

- (a) A primary or satellite airport with an operating control tower. Two-way radio communications must be established and maintained with the control tower, and thereafter as instructed by ATC while operating in Class C airspace.
- (b) A satellite airport without an operating control tower. Two-way radio communications must be established as soon as practicable after departing with the ATC facility having jurisdiction over the Class C airspace.

5. **Aircraft Speed.** Unless otherwise authorized or required by ATC, no person may operate an aircraft at or below 2,500 feet above the surface within 4 nautical miles of the primary airport of a Class C airspace area at an indicated airspeed of more than 200 knots (230 mph).

d. **Air Traffic Services.** When two-way radio communications and radar contact are established, all VFR aircraft are:

- 1. Sequenced to the primary airport.
- 2. Provided Class C services within the Class C airspace and the outer area.
- 3. Provided basic radar services beyond the outer area on a workload permitting basis. This can be terminated by the controller if workload dictates.

e. **Aircraft Separation.** Separation is provided within the Class C airspace and the outer area after two-way radio communications and radar contact are established. VFR aircraft are separated from IFR aircraft within the Class C airspace by any of the following:

- 1. Visual separation.
- 2. 500 feet vertical separation.
- 3. Target resolution.
- 4. Wake turbulence separation will be provided to all aircraft operating:
 - (a) Behind and less than 1,000 feet below super or heavy aircraft,
 - (b) To small aircraft operating behind and less than 500 feet below B757 aircraft, and
 - (c) To small aircraft following a large aircraft on final approach.

NOTE:

- 1. *Separation and sequencing of VFR aircraft will be suspended in the event of a radar outage as this service is dependent on radar. The pilot will be advised that the service is not available and issued wind, runway information and the time or place to contact the tower.*
- 2. *Pilot participation is voluntary within the outer area and can be discontinued, within the outer area, at the pilot's request. Class C services will be provided in the outer area unless the pilot requests termination of the service.*

US 3-2
SECTION 2. CONTROLLED AIRSPACE

3. Some facilities provide Class C services only during published hours. At other times, terminal IFR radar service will be provided. It is important to note that the communications and transponder/ADS-B requirements are dependent on the class of airspace established outside of the published hours.

f. Secondary Airports

1. In some locations Class C airspace may overlie the Class D surface area of a secondary airport. In order to allow that control tower to provide service to aircraft, portions of the overlapping Class C airspace may be procedurally excluded when the secondary airport tower is in operation. Aircraft operating in these procedurally excluded areas will only be provided airport traffic control services when in communication with the secondary airport tower.
2. Aircraft proceeding inbound to a satellite airport will be terminated at a sufficient distance to allow time to change to the appropriate tower or advisory frequency. Class C services to these aircraft will be discontinued when the aircraft is instructed to contact the tower or change to advisory frequency.
3. Aircraft departing secondary controlled airports will not receive Class C services until they have been radar identified and two-way communications have been established with the Class C airspace facility.
4. This program is not to be interpreted as relieving pilots of their responsibilities to see and avoid other traffic operating in basic VFR weather conditions, to adjust their operations and flight path as necessary to preclude serious wake encounters, to maintain appropriate terrain and obstruction clearance or to remain in weather conditions equal to or better than the minimums required by 14 CFR Section 91.155. Approach control should be advised and a revised clearance or instruction obtained when compliance with an assigned route, heading and/or altitude is likely to compromise pilot responsibility with respect to terrain and obstruction clearance, vortex exposure, and weather minimums.

g. Class C Airspace Areas by State

These states currently have designated Class C airspace areas that are depicted on sectional charts. [Also published on Jeppesen Enroute and Area Charts.] Pilots should consult current sectional charts and NOTAMs for the latest information on services available. [Also See Jeppesen Enroute and Area Charts.] Pilots should be aware that some Class C airspace underlies or is adjacent to Class B airspace. (See TBL 3-2-1.)

3-2-5 CLASS D AIRSPACE

- a. **Definition.** Generally, Class D airspace extends upward from the surface to 2,500 feet above the airport elevation (charted in MSL) surrounding those airports that have an operational control tower. The configuration of each Class D airspace area is individually tailored and when instrument procedures are published, the airspace will normally be designed to contain the procedures.

US 3-2

SECTION 2. CONTROLLED AIRSPACE

1. Class D surface areas may be designated as full-time (24 hour tower operations) or part-time. Part-time Class D effective times are published in the Chart Supplement U.S.
2. Where a Class D surface area is part-time, the airspace may revert to either a Class E surface area (see paragraph 3-2-6e1) or Class G airspace. When a part-time Class D surface area changes to Class G, the surface area becomes Class G airspace up to, but not including, the overlying controlled airspace.

NOTE 1: *The airport listing in the Chart Supplement U.S. will state the part-time surface area status (for example, “other times CLASS E” or “other times CLASS G”).*

NOTE 2: *Normally, the overlying controlled airspace is the Class E transition area airspace that begins at either 700 feet AGL (charted as magenta vignette) or 1200 feet AGL (charted as blue vignette). This may be determined by consulting the applicable VFR Sectional or Terminal Area Charts.*

b. Operating Rules and Pilot/Equipment Requirements:

1. **Pilot Certification.** No specific certification required.
2. **Equipment.** Unless otherwise authorized by ATC, an operable two-way radio is required.
3. **Arrival or Through Flight Entry Requirements.** Two-way radio communication must be established with the ATC facility providing ATC services prior to entry and thereafter maintain those communications while in the Class D airspace. Pilots of arriving aircraft should contact the control tower on the publicized frequency and give their position, altitude, destination, and any request(s). Radio contact should be initiated far enough from the Class D airspace boundary to preclude entering the Class D airspace before two-way radio communications are established.

NOTE:

1. *If the controller responds to a radio call with, “[aircraft callsign] standby,” radio communications have been established and the pilot can enter the Class D airspace.*
2. *If workload or traffic conditions prevent immediate entry into Class D airspace, the controller will inform the pilot to remain outside the Class D airspace until conditions permit entry.*

EXAMPLE:

1. “[Aircraft callsign] remain outside the Class Delta airspace and standby.”

It is important to understand that if the controller responds to the initial radio call without using the aircraft callsign, radio communications have not been established and the pilot may not enter the Class D airspace.

2. “Aircraft calling Manassas tower standby.”

At those airports where the control tower does not operate 24 hours a day, the operating hours of the tower will be listed on the appropriate charts and in the

US 3-2

SECTION 2. CONTROLLED AIRSPACE

Chart Supplement U.S. During the hours the tower is not in operation, the Class E surface area rules or a combination of Class E rules to 700 feet above ground level and Class G rules to the surface will become applicable. Check the Chart Supplement U.S. for specifics.

4. Departures from:

- (a) A primary or satellite airport with an operating control tower. Two-way radio communications must be established and maintained with the control tower, and thereafter as instructed by ATC while operating in the Class D airspace.
- (b) A satellite airport without an operating control tower. Two-way radio communications must be established as soon as practicable after departing with the ATC facility having jurisdiction over the Class D airspace as soon as practicable after departing.

5. Aircraft Speed. Unless otherwise authorized or required by ATC, no person may operate an aircraft at or below 2,500 feet above the surface within 4 nautical miles of the primary airport of a Class D airspace area at an indicated airspeed of more than 200 knots (230 mph).

c. Class D airspace areas are depicted on Sectional and Terminal charts with blue segmented lines, and on IFR En Route Lows with a boxed [D].

d. Surface area arrival extensions:

- 1. Class D surface area arrival extensions for instrument approach procedures may be Class D or Class E airspace. As a general rule, if all extensions are 2 miles or less, they remain part of the Class D surface area. However, if any one extension is greater than 2 miles, then all extensions will be Class E airspace.
- 2. Surface area arrival extensions are effective during the published times of the surface area. For part-time Class D surface areas that revert to Class E airspace, the arrival extensions will remain in effect as Class E airspace. For part-time Class D surface areas that change to Class G airspace, the arrival extensions will become Class G at the same time.

e. **Separation for VFR Aircraft.** No separation services are provided to VFR aircraft.

3-2-6 CLASS E AIRSPACE

a. **Definition.** Class E airspace is controlled airspace that is designated to serve a variety of terminal or en route purposes as described in this paragraph.

b. Operating Rules and Pilot/Equipment Requirements:

1. **Pilot Certification.** No specific certification required.

2. **Equipment.** Unless otherwise authorized by ATC:

- (a) An operable radar beacon transponder with automatic altitude reporting capability and operable ADS-B Out equipment are required at and above 10,000 feet MSL

US 3-2

SECTION 2. CONTROLLED AIRSPACE

within the 48 contiguous states and the District of Columbia, excluding the airspace at and below 2,500 feet above the surface, and

- (b) Operable ADS-B Out equipment at and above 3,000 feet MSL over the Gulf of Mexico from the coastline of the United States out to 12 nautical miles.

NOTE: The airspace described in (b) is specified in 14 CFR §91.225 for ADS-B Out requirements. However, 14 CFR §91.215 does not include this airspace for transponder requirements.

3. Arrival or Through Flight Entry Requirements. No specific requirements.

- c. **Charts.** Class E airspace below 14,500 feet MSL is charted on Sectional, Terminal, and IFR Enroute Low Altitude charts.

- d. **Vertical limits.** Except where designated at a lower altitude (see paragraph 3-2-6e, below, for specifics), Class E airspace in the United States consists of:

1. The airspace extending upward from 14,500 feet MSL to, but not including, 18,000 feet MSL overlying the 48 contiguous states, the District of Columbia and Alaska, including the waters within nautical 12 miles from the coast of the 48 contiguous states and Alaska; excluding:

- (a) The Alaska peninsula west of longitude 160°00'00"W.; and

- (b) The airspace below 1,500 feet above the surface of the earth unless specifically designated lower (for example, in mountainous terrain higher than 13,000 feet MSL).

2. The airspace above FL 600 is Class E airspace.

- e. **Functions of Class E Airspace.** Class E airspace may be designated for the following purposes:

1. **Surface area designated for an airport where a control tower is not in operation.**

Class E surface areas extend upward from the surface to a designated altitude, or to the adjacent or overlying controlled airspace. The airspace will be configured to contain all instrument procedures.

- (a) To qualify for a Class E surface area, the airport must have weather observation and reporting capability, and communications capability must exist with aircraft down to the runway surface.

- (b) A Class E surface area may also be designated to accommodate part-time operations at a Class C or Class D airspace location (for example, those periods when the control tower is not in operation).

- (c) Pilots should refer to the airport page in the applicable Chart Supplement U.S. for surface area status information.

2. **Extension to a surface area.** Class E airspace may be designated as extensions to Class B, Class C, Class D, and Class E surface areas. Class E airspace extensions begin at the surface and extend up to the overlying controlled airspace. The extensions

US 3-2

SECTION 2. CONTROLLED AIRSPACE

provide controlled airspace to contain standard instrument approach procedures without imposing a communications requirement on pilots operating under VFR. Surface area arrival extensions become part of the surface area and are in effect during the same times as the surface area.

NOTE: When a Class C or Class D surface area is not in effect continuously (for example, where a control tower only operates part-time), the surface area airspace will change to either a Class E surface area or Class G airspace. In such cases, the "Airspace" entry for the airport in the Chart Supplement U.S. will state "other times Class E" or "other times Class G." When a part-time surface area changes to Class E airspace, the Class E arrival extensions will remain in effect as Class E airspace. If a part-time Class C, Class D, or Class E surface area becomes Class G airspace, the arrival extensions will change to Class G at the same time.

3. **Airspace used for transition.** Class E airspace areas may be designated for transitioning aircraft to/from the terminal or en route environment.
 - (a) Class E transition areas extend upward from either 700 feet AGL (shown as magenta vignette on sectional charts) or 1,200 feet AGL (blue vignette) and are designated for airports with an approved instrument procedure.
 - (b) The 700-foot/1200-foot AGL Class E airspace transition areas remain in effect continuously, regardless of airport operating hours or surface area status.

NOTE: Do not confuse the 700-foot and 1200-foot Class E transition areas with surface areas or surface area extensions.

4. **En Route Domestic Areas.** There are Class E airspace areas that extend upward from a specified altitude and are en route domestic airspace areas that provide controlled airspace in those areas where there is a requirement to provide IFR en route ATC services but the Federal airway system is inadequate.
5. **Federal Airways and Low-Altitude RNAV Routes.** Federal airways and low-altitude RNAV routes are Class E airspace areas and, unless otherwise specified, extend upward from 1,200 feet AGL to, but not including, 18,000 feet MSL.
 - (a) Federal airways consist of Low/Medium Frequency (L/MF) airways (colored Federal airways) and VOR Federal airways.
 - (1) L/MF airways are based on non-directional beacons (NDB) and are identified as green, red, amber, or blue.
 - (2) VOR Federal airways are based on VOR/VORTAC facilities and are identified by a "V" prefix.
 - (b) Low-altitude RNAV routes consist of T-routes and helicopter RNAV routes (TK-routes).

NOTE: See AIM Paragraph 5-3-4, *Airways and Route Systems*, for more details and charting information.

US 3-2**SECTION 2. CONTROLLED AIRSPACE**

6. **Offshore Airspace Areas.** There are Class E airspace areas that extend upward from a specified altitude to, but not including, 18,000 feet MSL and are designated as offshore airspace areas. These areas provide controlled airspace beyond 12 miles from the coast of the U.S. in those areas where there is a requirement to provide IFR en route ATC services and within which the U.S. is applying domestic procedures.
- f. **Separation for VFR Aircraft.** No separation services are provided to VFR aircraft.

US 3-3
SECTION 3. CLASS G AIRSPACE
3-3-1 GENERAL

Class G airspace (uncontrolled) is that portion of airspace that has not been designated as Class A, Class B, Class C, Class D, or Class E airspace.

3-3-2 VFR REQUIREMENTS

Rules governing VFR flight have been adopted to assist the pilot in meeting the responsibility to see and avoid other aircraft. Minimum flight visibility and distance from clouds required for VFR flight are contained in 14 CFR Section 91.155. (See TBL 3-1-1.)

3-3-3 IFR REQUIREMENTS

- a. Title 14 CFR specifies the pilot and aircraft equipment requirements for IFR flight. Pilots are reminded that in addition to altitude or flight level requirements, 14 CFR Section 91.177 includes a requirement to remain at least 1,000 feet (2,000 feet in designated mountainous terrain) above the highest obstacle within a horizontal distance of 4 nautical miles from the course to be flown.
- b. IFR Altitudes. (See TBL 3-3-1.)

TABLE 3-3-1 IFR Altitudes Class G Airspace

If your magnetic course (ground track) is:	And you are below 18,000 feet MSL, fly:
0° to 179°	Odd thousands MSL, (3,000; 5,000; 7,000, etc.)
180° to 359°	Even thousands MSL, (2,000; 4,000; 6,000, etc.)

US 3-4

SECTION 4. SPECIAL USE AIRSPACE

3-4-1 GENERAL

- a. Special use airspace (SUA) consists of that airspace wherein activities must be confined because of their nature, or wherein limitations are imposed upon aircraft operations that are not a part of those activities, or both. SUA areas are depicted on aeronautical charts, except for controlled firing areas (CFA), temporary military operations areas (MOA), and temporary restricted areas.
- b. Prohibited and restricted areas are regulatory special use airspace and are established in 14 CFR Part 73 through the rulemaking process.
- c. Warning areas, MOAs, alert areas, CFAs, and national security areas (NSA) are nonregulatory special use airspace.
- d. Special use airspace descriptions (except CFAs) are contained in FAA Order JO 7400.10, Special Use Airspace.
- e. Permanent SUA (except CFAs) is charted on Sectional Aeronautical, VFR Terminal Area, and applicable En Route charts, and include the hours of operation, altitudes, and the controlling agency.

NOTE: For temporary restricted areas and temporary MOAs, pilots should review the Domestic Notices found on the Federal NOTAM System (FNS) NOTAM Search website under External Links or the Air Traffic Plans and Publications website, the FAA SUA website, and/or contact the appropriate overlying ATC facility to determine the effect of non-depicted SUA areas along their routes of flight.

3-4-2 PROHIBITED AREAS

Prohibited areas contain airspace of defined dimensions identified by an area on the surface of the earth within which the flight of aircraft is prohibited. Such areas are established for security or other reasons associated with the national welfare. These areas are published in the Federal Register and are depicted on aeronautical charts.

3-4-3 RESTRICTED AREAS

- a. Restricted areas contain airspace identified by an area on the surface of the earth within which the flight of aircraft, while not wholly prohibited, is subject to restrictions. Activities within these areas must be confined because of their nature or limitations imposed upon aircraft operations that are not a part of those activities or both. Restricted areas denote the existence of unusual, often invisible, hazards to aircraft such as artillery firing, aerial gunnery, or guided missiles. Penetration of restricted areas without authorization from the using or controlling agency may be extremely hazardous to the aircraft and its occupants. Restricted areas are published in the Federal Register and constitute 14 CFR Part 73.

US 3-4

SECTION 4. SPECIAL USE AIRSPACE

- b. ATC facilities apply the following procedures when aircraft are operating on an IFR clearance (including those cleared by ATC to maintain VFR-on-top) via a route which lies within joint-use restricted airspace.
1. If the restricted area is not active and has been released to the controlling agency (FAA), the ATC facility will allow the aircraft to operate in the restricted airspace without issuing specific clearance for it to do so.
 2. If the restricted area is active and has not been released to the controlling agency (FAA), the ATC facility will issue a clearance which will ensure the aircraft avoids the restricted airspace unless it is on an approved altitude reservation mission or has obtained its own permission to operate in the airspace and so informs the controlling facility.

NOTE: *The above apply only to joint-use restricted airspace and not to prohibited and non-joint-use airspace. For the latter categories, the ATC facility will issue a clearance so the aircraft will avoid the restricted airspace unless it is on an approved altitude reservation mission or has obtained its own permission to operate in the airspace and so informs the controlling facility.*

- c. Permanent restricted areas are charted on Sectional Aeronautical, VFR Terminal Area, and the appropriate En Route charts.

NOTE: *Temporary restricted areas are not charted.*

3-4-4 WARNING AREAS

A warning area is airspace of defined dimensions, extending from three nautical miles outward from the coast of the U.S., that contains activity that may be hazardous to nonparticipating aircraft. The purpose of such warning areas is to warn nonparticipating pilots of the potential danger. A warning area may be located over domestic or international waters or both.

3-4-5 MILITARY OPERATIONS AREAS

- a. MOAs consist of airspace of defined vertical and lateral limits established for the purpose of separating certain military training activities from IFR traffic. Whenever a MOA is being used, nonparticipating IFR traffic may be cleared through a MOA if IFR separation can be provided by ATC. Otherwise, ATC will reroute or restrict nonparticipating IFR traffic.
- b. Examples of activities conducted in MOAs include, but are not limited to: air combat tactics, air intercepts, aerobatics, formation training, and low-altitude tactics. Military pilots flying in an active MOA are exempted from the provisions of 14 CFR Section 91.303(c) and (d) which prohibits aerobatic flight within Class D and Class E surface areas, and within Federal airways. Additionally, the Department of Defense has been issued an authorization to operate aircraft at indicated airspeeds in excess of 250 knots below 10,000 feet MSL within active MOAs.
- c. Pilots operating under VFR should exercise extreme caution while flying within a MOA when military activity is being conducted. The activity status (active/inactive) of MOAs may change frequently. Therefore, pilots should contact any FSS within 100 miles of the area to obtain

US 3-4

SECTION 4. SPECIAL USE AIRSPACE

accurate real-time information concerning the MOA hours of operation. Prior to entering an active MOA, pilots should contact the controlling agency for traffic advisories.

- d. Permanent MOAs are charted on Sectional Aeronautical, VFR Terminal Area, and the appropriate En Route Low Altitude charts.

NOTE: *Temporary MOAs are not charted.*

3-4-6 ALERT AREAS

Alert areas are depicted on aeronautical charts to inform nonparticipating pilots of areas that may contain a high volume of pilot training or an unusual type of aerial activity. Pilots should be particularly alert when flying in these areas. All activity within an alert area must be conducted in accordance with CFRs, without waiver, and pilots of participating aircraft as well as pilots transiting the area must be equally responsible for collision avoidance.

3-4-7 CONTROLLED FIRING AREAS

CFAs contain activities which, if not conducted in a controlled environment, could be hazardous to nonparticipating aircraft. The distinguishing feature of the CFA, as compared to other special use airspace, is that its activities are suspended immediately when spotter aircraft, radar, or ground lookout positions indicate an aircraft might be approaching the area. There is no need to chart CFAs since they do not cause a nonparticipating aircraft to change its flight path.

3-4-8 NATIONAL SECURITY AREAS

NSAs consist of airspace of defined vertical and lateral dimensions established at locations where there is a requirement for increased security and safety of ground facilities. Pilots are requested to voluntarily avoid flying through the depicted NSA. When it is necessary to provide a greater level of security and safety, flight in NSAs may be temporarily prohibited by regulation under the provisions of 14 CFR Section 99.7. Regulatory prohibitions will be issued by System Operations Security and disseminated via NOTAM. Inquiries about NSAs should be directed to System Operations Security.

REFERENCE—*AIM, Para 5-6-1, National Security.*

3-4-9 OBTAINING SPECIAL USE AIRSPACE STATUS

- a. Pilots can request the status of SUA by contacting the using or controlling agency. The frequency for the controlling agency is tabulated in the margins of the applicable IFR and VFR charts.
- b. An airspace NOTAM will be issued for SUA when the SUA airspace (permanent and/or temporary) requires a NOTAM for activation. Pilots should check ARTCC NOTAMs for airspace activation.
- c. **Special Use Airspace Information Service (SUAIS) (Alaska Only).** The SUAIS is a 24-hour service operated by the military that provides civilian pilots, flying VFR, with information regarding military flight operations in certain MOAs and restricted airspace within central Alaska. The service provides “near real time” information on military flight activity in the inte-

US 3-4**SECTION 4. SPECIAL USE AIRSPACE**

rior Alaska MOA and Restricted Area complex. SUAIS also provides information on artillery firing, known helicopter operations, and unmanned aerial vehicle operations. Pilots flying VFR are encouraged to use SUAIS. See the Alaska Chart Supplement for hours of operation, phone numbers, and radio frequencies.

- d. Special use airspace scheduling data for preflight planning is available via the FAA SUA website.

US 3-5

SECTION 5. OTHER AIRSPACE AREAS

3-5-1 AIRPORT ADVISORY/INFORMATION SERVICES

a. There are two advisory type services available at selected airports.

1. Local Airport Advisory (LAA) service is available only in Alaska and is operated within 10 statute miles of an airport where a control tower is not operating but where a FSS is located on the airport. At such locations, the FSS provides a complete local airport advisory service to arriving and departing aircraft. During periods of fast changing weather the FSS will automatically provide Final Guard as part of the service from the time the aircraft reports “on-final” or “taking-the-active-runway” until the aircraft reports “on-the-ground” or “airborne.”

NOTE: *Current policy, when requesting remote ATC services, requires that a pilot monitor the automated weather broadcast at the landing airport prior to requesting ATC services. The FSS automatically provides Final Guard, when appropriate, during LAA/ Remote Airport Advisory (RAA) operations. Final Guard is a value added wind/altimeter monitoring service, which provides an automatic wind and altimeter check during active weather situations when the pilot reports on-final or taking the active runway. During the landing or take-off operation when the winds or altimeter are actively changing the FSS will blind broadcast significant changes when the specialist believes the change might affect the operation. Pilots should acknowledge the first wind/altimeter check but due to cockpit activity no acknowledgement is expected for the blind broadcasts. It is prudent for a pilot to report on-the-ground or airborne to end the service.*

2. Remote Airport Information Service (RAIS) is provided in support of short term special events like small to medium fly-ins. The service is advertised by NOTAM D only. The FSS will not have access to a continuous readout of the current winds and altimeter; therefore, RAIS does not include weather and/or Final Guard service. However, known traffic, special event instructions, and all other services are provided.

NOTE: *The airport authority and/or manager should request RAIS support on official letterhead directly with the manager of the FSS that will provide the service at least 60 days in advance. Approval authority rests with the FSS manager and is based on workload and resource availability.*

REFERENCE—AIM, Paragraph 4-1-9, *Traffic Advisory Practices at Airports Without Operating Control Towers.*

- b. It is not mandatory that pilots participate in the Airport Advisory programs. Participation enhances safety for everyone operating around busy GA airports; therefore, everyone is encouraged to participate and provide feedback that will help improve the program.

3-5-2 MILITARY TRAINING ROUTES

- a. National security depends largely on the deterrent effect of our airborne military forces. To be proficient, the military services must train in a wide range of airborne tactics. One phase of this training involves “low level” combat tactics. The required maneuvers and high speeds are such that they may occasionally make the see-and-avoid aspect of VFR flight more difficult without increased vigilance in areas containing such operations. In an effort to ensure

US 3-5

SECTION 5. OTHER AIRSPACE AREAS

the greatest practical level of safety for all flight operations, the Military Training Route (MTR) program was conceived.

- b. The MTR program is a joint venture by the FAA and the Department of Defense (DOD). MTRs are mutually developed for use by the military for the purpose of conducting low-altitude, high-speed training. The routes above 1,500 feet AGL are developed to be flown, to the maximum extent possible, under IFR. The routes at 1,500 feet AGL and below are generally developed to be flown under VFR.
 - c. Generally, MTRs are established below 10,000 feet MSL for operations at speeds in excess of 250 knots. However, route segments may be defined at higher altitudes for purposes of route continuity. For example, route segments may be defined for descent, climbout, and mountainous terrain. There are IFR and VFR routes as follows:
 1. **IFR Military Training Routes-(IR).** Operations on these routes are conducted in accordance with IFR regardless of weather conditions.
 2. **VFR Military Training Routes-(VR).** Operations on these routes are conducted in accordance with VFR except flight visibility must be 5 miles or more; and flights must not be conducted below a ceiling of less than 3,000 feet AGL.
 - d. Military training routes will be identified and charted as follows:
 1. **Route identification.**
 - (a) MTRs with no segment above 1,500 feet AGL must be identified by four number characters; e.g., IR1206, VR1207.
 - (b) MTRs that include one or more segments above 1,500 feet AGL must be identified by three number characters; e.g., IR206, VR207.
 - (c) Alternate IR/VR routes or route segments are identified by using the basic/principal route designation followed by a letter suffix, e.g., IR008A, VR1007B, etc.
 2. **Route charting.**
 - (a) **IFR Enroute Low Altitude Chart.** This chart will depict all IR routes and all VR routes that accommodate operations above 1,500 feet AGL. [Military Training Routes are not charted on Jeppesen Charts.]
 - (b) **VFR Sectional Aeronautical Charts.** These charts will depict military training activities such as IR and VR information.
 - (c) **Area Planning (AP/1B) Chart (DOD Flight Information Publication-FLIP).** This chart is published by the National Geospatial-Intelligence Agency (NGA) primarily for military users and contains detailed information on both IR and VR routes.
- REFERENCE**—AIM, Paragraph 9-1-5, Subparagraph a, National Geospatial-Intelligence Agency (NGA) Products.
- e. The FLIP contains charts and narrative descriptions of these routes. To obtain this publication contact:

US 3-5

SECTION 5. OTHER AIRSPACE AREAS

Defense Logistics Agency for Aviation

Mapping Customer Operations (DLA AVN/QAM)

Address: 8000 Jefferson Davis Highway

Richmond

VA

23297-5339

Tel: Toll free phone: 1-800-826-0342

Commercial: 804-279-6500

MTR information from the FLIP is available for pilot briefings through Flight Service. (See subparagraph f below.)

f. Availability of MTR information.

1. Pilots may obtain preflight MTR information through Flight Service (see paragraph 5-1-1, Preflight Preparation).

2. MTR routes are depicted on IFR En Route Low Altitude Charts and VFR Sectional Charts, which are available for free download on the FAA website at https://www.faa.gov/air_traffic/flight_info/aeronav/digital_products/.

g. Nonparticipating aircraft are not prohibited from flying within an MTR; however, extreme vigilance should be exercised when conducting flight through or near these routes. Pilots, while inflight, should contact the FSS within 100 NM of a particular MTR to obtain current information or route usage in their vicinity. Information available includes times of scheduled activity, altitudes in use on each route segment, and actual route width. Route width varies for each MTR and can extend several miles on either side of the charted MTR centerline. Route width information for IFR Military Training Route (IR) and VFR Military Training Route (VR) MTRs is also available in the FLIP AP/1B along with additional MTR (slow routes/air refueling routes) information. When requesting MTR information, pilots should give the FSS their position, route of flight, and destination in order to reduce frequency congestion and permit the FSS specialist to identify the MTR which could be a factor.

3-5-3 TEMPORARY FLIGHT RESTRICTIONS

a. **General.** This paragraph describes the types of conditions under which the FAA may impose temporary flight restrictions. It also explains which FAA elements have been delegated authority to issue a temporary flight restrictions NOTAM and lists the types of responsible agencies/offices from which the FAA will accept requests to establish temporary flight restrictions. The 14 CFR is explicit as to what operations are prohibited, restricted, or allowed in a temporary flight restrictions area. Pilots are responsible to comply with 14 CFR Sections 91.137, 91.138, 91.141 and 91.143 when conducting flight in an area where a temporary flight restrictions area is in effect, and should check appropriate NOTAMs during flight planning.

b. **The purpose for establishing a temporary flight restrictions area is to:**

US 3-5

SECTION 5. OTHER AIRSPACE AREAS

1. Protect persons and property in the air or on the surface from an existing or imminent hazard associated with an incident on the surface when the presence of low flying aircraft would magnify, alter, spread, or compound that hazard (14 CFR Section 91.137(a)(1));
 2. Provide a safe environment for the operation of disaster relief aircraft (14 CFR Section 91.137(a)(2)); or
 3. Prevent an unsafe congestion of sightseeing aircraft above an incident or event which may generate a high degree of public interest (14 CFR Section 91.137(a)(3)).
 4. Protect declared national disasters for humanitarian reasons in the State of Hawaii (14 CFR Section 91.138).
 5. Protect the President, Vice President, or other public figures (14 CFR Section 91.141).
 6. Provide a safe environment for space agency operations (14 CFR Section 91.143).
- c. Except for hijacking situations, when the provisions of 14 CFR Section 91.137(a)(1) or (a)(2) are necessary, a temporary flight restrictions area will only be established by or through the area manager at the Air Route Traffic Control Center (ARTCC) having jurisdiction over the area concerned. A temporary flight restrictions NOTAM involving the conditions of 14 CFR Section 91.137(a)(3) will be issued at the direction of the service area office director having oversight of the airspace concerned. When hijacking situations are involved, a temporary flight restrictions area will be implemented through the TSA Aviation Command Center. The appropriate FAA air traffic element, upon receipt of such a request, will establish a temporary flight restrictions area under 14 CFR Section 91.137(a)(1).
- d. The FAA accepts recommendations for the establishment of a temporary flight restrictions area under 14 CFR Section 91.137(a)(1) from military major command headquarters, regional directors of the Office of Emergency Planning, Civil Defense State Directors, State Governors, or other similar authority. For the situations involving 14 CFR Section 91.137(a)(2), the FAA accepts recommendations from military commanders serving as regional, sub-regional, or Search and Rescue (SAR) coordinators; by military commanders directing or coordinating air operations associated with disaster relief; or by civil authorities directing or coordinating organized relief air operations (includes representatives of the Office of Emergency Planning, U.S. Forest Service, and State aeronautical agencies). Appropriate authorities for a temporary flight restrictions establishment under 14 CFR Section 91.137(a)(3) are any of those listed above or by State, county, or city government entities.
- e. The type of restrictions issued will be kept to a minimum by the FAA consistent with achievement of the necessary objective. Situations which warrant the extreme restrictions of 14 CFR Section 91.137(a)(1) include, but are not limited to: toxic gas leaks or spills, flammable agents, or fumes which if fanned by rotor or propeller wash could endanger persons or property on the surface, or if entered by an aircraft could endanger persons or property in the air; imminent volcano eruptions which could endanger airborne aircraft and occupants; nuclear accident or incident; and hijackings. Situations which warrant the restrictions associated with 14 CFR Section 91.137(a)(2) include: forest fires which are being fought by releasing fire retardants from aircraft; and aircraft relief activities following a disaster (earthquake, tidal

US 3-5

SECTION 5. OTHER AIRSPACE AREAS

wave, flood, etc.). 14 CFR Section 91.137(a)(3) restrictions are established for events and incidents that would attract an unsafe congestion of sightseeing aircraft.

- f. The amount of airspace needed to protect persons and property or provide a safe environment for rescue/relief aircraft operations is normally limited to within 2,000 feet above the surface and within a 3-nautical-mile radius. Incidents occurring within Class B, Class C, or Class D airspace will normally be handled through existing procedures and should not require the issuance of a temporary flight restrictions NOTAM. Temporary flight restrictions affecting airspace outside of the U.S. and its territories and possessions are issued with verbiage excluding that airspace outside of the 12-mile coastal limits.
- g. The FSS nearest the incident site is normally the “coordination facility.” When FAA communications assistance is required, the designated FSS will function as the primary communications facility for coordination between emergency control authorities and affected aircraft. The ARTCC may act as liaison for the emergency control authorities if adequate communications cannot be established between the designated FSS and the relief organization. For example, the coordination facility may relay authorizations from the on-scene emergency response official in cases where news media aircraft operations are approved at the altitudes used by relief aircraft.
- h. ATC may authorize operations in a temporary flight restrictions area under its own authority only when flight restrictions are established under 14 CFR Section 91.137(a)(2) and (a)(3). The appropriate ARTCC/airport traffic control tower manager will, however, ensure that such authorized flights do not hamper activities or interfere with the event for which restrictions were implemented. However, ATC will not authorize local IFR flights into the temporary flight restrictions area.
- i. To preclude misunderstanding, the implementing NOTAM will contain specific and formatted information. The facility establishing a temporary flight restrictions area will format a NOTAM beginning with the phrase “FLIGHT RESTRICTIONS” followed by: the location of the temporary flight restrictions area; the effective period; the area defined in statute miles; the altitudes affected; the FAA coordination facility and commercial telephone number; the reason for the temporary flight restrictions; the agency directing any relief activities and its commercial telephone number; and other information considered appropriate by the issuing authority.

EXAMPLE:

1. 14 CFR Section 91.137(a)(1):

The following NOTAM prohibits all aircraft operations except those specified in the NOTAM.

Flight restrictions Matthews, Virginia, effective immediately until 9610211200. Pursuant to 14 CFR Section 91.137(a)(1) temporary flight restrictions are in effect. Rescue operations in progress. Only relief aircraft operations under the direction of the Department of Defense are authorized in the airspace at and below 5,000 feet MSL within a 2-nautical-mile radius of Laser AFB, Matthews, Virginia. Commander, Laser AFB, in charge (897)

US 3-5

SECTION 5. OTHER AIRSPACE AREAS

946-5543 (122.4). Steenson FSS (792) 555-6141 (123.1) is the FAA coordination facility.

2. 14 CFR Section 91.137(a)(2):

The following NOTAM permits flight operations in accordance with 14 CFR Section 91.137(a)(2). The on-site emergency response official to authorize media aircraft operations below the altitudes used by the relief aircraft.

Flight restrictions 25 miles east of Bransome, Idaho, effective immediately until 9601202359 UTC. Pursuant to 14 CFR Section 91.137(a)(2) temporary flight restrictions are in effect within a 4-nautical-mile radius of the intersection of county roads 564 and 315 at and below 3,500 feet MSL to provide a safe environment for fire fighting aircraft operations. Davis County sheriff's department (792) 555-8122 (122.9) is in charge of on-scene emergency response activities. Glivings FSS (792) 555-1618 (122.2) is the FAA coordination facility.

3. 14 CFR Section 91.137(a)(3):

The following NOTAM prohibits sightseeing aircraft operations.

Flight restrictions Brown, Tennessee, due to olympic activity. Effective 9606181100 UTC until 9607190200 UTC. Pursuant to 14 CFR Section 91.137(a)(3) temporary flight restrictions are in effect within a 3-nautical-mile radius of N355783/W835242 and Volunteer VORTAC 019 degree radial 3.7 DME fix at and below 2,500 feet MSL. Norton FSS (423) 555-6742(126.6) is the FAA coordination facility.

4. 14 CFR Section 91.138:

The following NOTAM prohibits all aircraft except those operating under the authorization of the official in charge of associated emergency or disaster relief response activities, aircraft carrying law enforcement officials, aircraft carrying personnel involved in an emergency or legitimate scientific purposes, carrying properly accredited news media, and aircraft operating in accordance with an ATC clearance or instruction.

Flight restrictions Kapalua, Hawaii, effective 9605101200 UTC until 9605151500 UTC. Pursuant to 14 CFR Section 91.138 temporary flight restrictions are in effect within a 3-nautical-mile radius of N205778/W1564038 and Maui/OGG/VORTAC 275 degree radial at 14.1 nautical miles. John Doe 808-757-4469 or 122.4 is in charge of the operation. Honolulu/HNL 808-757-4470 (123.6) FSS is the FAA coordination facility.

5. 14 CFR Section 91.141:

The following NOTAM prohibits all aircraft.

Flight restrictions Stillwater, Oklahoma, June 21, 1996. Pursuant to 14 CFR Section 91.141 aircraft flight operations are prohibited within a 3-nautical-mile radius, below 2000 feet AGL of N360962/W970515 and the Stillwater/SWO/VOR/DME 176 degree radial 3.8- nautical-mile fix from 1400 local time to 1700 local time June 21, 1996, unless otherwise authorized by ATC.

6. 14 CFR Section 91.143:

US 3-5

SECTION 5. OTHER AIRSPACE AREAS

The following NOTAM prohibits any aircraft of U.S. registry, or pilot any aircraft under the authority of an airman certificate issued by the FAA.

Kennedy Space center space operations area effective immediately until 9610152100 UTC. Pursuant to 14 CFR Section 91.143, flight operations conducted by FAA certificated pilots or conducted in aircraft of U.S. registry are prohibited at any altitude from surface to unlimited, within the following area 30-nautical-mile radius of the Melbourne/MLB/VORTAC 010 degree radial 21-nautical-mile fix. St. Petersburg, Florida/PIE/FSS 813-545-1645 (122.2) is the FAA coordination facility and should be contacted for the current status of any airspace associated with the space shuttle operations. This airspace encompasses R2933, R2932, R2931, R2934, R2935, W497A and W158A. Additional warning and restricted areas will be active in conjunction with the operations. Pilots must consult all NOTAMs regarding this operation.

3-5-4 PARACHUTE JUMP AIRCRAFT OPERATIONS

- a. Procedures relating to parachute jump areas are contained in 14 CFR Part 105. Tabulations of parachute jump areas in the U.S. are contained in the Chart Supplement U.S.
- b. Pilots of aircraft engaged in parachute jump operations are reminded that all reported altitudes must be with reference to mean sea level, or flight level, as appropriate, to enable ATC to provide meaningful traffic information.
- c. Parachute operations in the vicinity of an airport without an operating control tower — there is no substitute for alertness while in the vicinity of an airport. It is essential that pilots conducting parachute operations be alert, look for other traffic, and exchange traffic information as recommended in Paragraph 4-1-9, Traffic Advisory Practices at Airports Without Operating Control Towers. In addition, pilots should avoid releasing parachutes while in an airport traffic pattern when there are other aircraft in that pattern. Pilots should make appropriate broadcasts on the designated Common Traffic Advisory Frequency (CTAF), and monitor that CTAF until all parachute activity has terminated or the aircraft has left the area. Prior to commencing a jump operation, the pilot should broadcast the aircraft's altitude and position in relation to the airport, the approximate relative time when the jump will commence and terminate, and listen to the position reports of other aircraft in the area.

3-5-5 PUBLISHED VFR ROUTES

Published VFR routes for transitioning around, under and through complex airspace such as Class B airspace were developed through a number of FAA and industry initiatives. All of the following terms, i.e., "VFR Flyway" "VFR Corridor" and "Class B Airspace VFR Transition Route" have been used when referring to the same or different types of routes or airspace. The following paragraphs identify and clarify the functionality of each type of route, and specify where and when an ATC clearance is required.

a. VFR Flyways.

1. VFR Flyways and their associated Flyway Planning Charts were developed from the recommendations of a National Airspace Review Task Group. A VFR Flyway is defined as a general flight path not defined as a specific course, for use by pilots in planning

US 3-5
SECTION 5. OTHER AIRSPACE AREAS

flights into, out of, through or near complex terminal airspace to avoid Class B airspace. An ATC clearance is NOT required to fly these routes.

FIGURE 3-5-1
VFR Flyway Planning Chart

US 3-5

SECTION 5. OTHER AIRSPACE AREAS

2. VFR Flyways are depicted on the reverse side of some of the VFR Terminal Area Charts (TAC), commonly referred to as Class B airspace charts. (See FIG 3-5-1.) Eventually all TACs will include a VFR Flyway Planning Chart. These charts identify VFR flyways designed to help VFR pilots avoid major controlled traffic flows. They may further depict multiple VFR routings throughout the area which may be used as an alternative to flight within Class B airspace. The ground references provide a guide for improved visual navigation. These routes are not intended to discourage requests for VFR operations within Class B airspace but are designed solely to assist pilots in planning for flights under and around busy Class B airspace without actually entering Class B airspace.
3. It is very important to remember that these suggested routes are not sterile of other traffic. The entire Class B airspace, and the airspace underneath it, may be heavily congested with many different types of aircraft. Pilot adherence to VFR rules must be exercised at all times. Further, when operating beneath Class B airspace, communications must be established and maintained between your aircraft and any control tower while transiting the Class B, Class C, and Class D surface areas of those airports under Class B airspace.

b. VFR Corridors.

1. The design of a few of the first Class B airspace areas provided a corridor for the passage of uncontrolled traffic. A VFR corridor is defined as airspace through Class B airspace, with defined vertical and lateral boundaries, in which aircraft may operate without an ATC clearance or communication with air traffic control.
2. These corridors are, in effect, a “hole” through Class B airspace. (See FIG 3-5-2.) A classic example would be the corridor through the Los Angeles Class B airspace, which has been subsequently changed to Special Flight Rules airspace (SFR). A corridor is surrounded on all sides by Class B airspace and does not extend down to the surface like a VFR Flyway. Because of their finite lateral and vertical limits, and the volume of VFR traffic using a corridor, extreme caution and vigilance must be exercised.

US 3-5
SECTION 5. OTHER AIRSPACE AREASFIGURE 3-5-2
Class B Airspace

3. Because of the heavy traffic volume and the procedures necessary to efficiently manage the flow of traffic, it has not been possible to incorporate VFR corridors in the development or modifications of Class B airspace in recent years.

c. Class B Airspace VFR Transition Routes.

1. To accommodate VFR traffic through certain Class B airspace, such as Seattle, Phoenix and Los Angeles, Class B Airspace VFR Transition Routes were developed. A Class B Airspace VFR Transition Route is defined as a specific flight course depicted on a TAC for transiting a specific Class B airspace. These routes include specific ATC-assigned altitudes, and pilots must obtain an ATC clearance prior to entering Class B airspace on the route.
2. These routes, as depicted in FIG 3-5-3, are designed to show the pilot where to position the aircraft outside of, or clear of, the Class B airspace where an ATC clearance can normally be expected with minimal or no delay. Until ATC authorization is received, pilots must remain clear of Class B airspace. On initial contact, pilots should advise ATC of their position, altitude, route name desired, and direction of flight. After a clearance is received, pilots must fly the route as depicted and, most importantly, adhere to ATC instructions.

US 3-5
SECTION 5. OTHER AIRSPACE AREAS

FIGURE 3-5-3
VFR Transition Route

(Not to be used for navigation)

3-5-6 TERMINAL RADAR SERVICE AREA (TRSA)

- Background.** TRSAs were originally established as part of the Terminal Radar Program at selected airports. TRSAs were never controlled airspace from a regulatory standpoint because the establishment of TRSAs was never subject to the rulemaking process; conse-

US 3-5

SECTION 5. OTHER AIRSPACE AREAS

quently, TRSAs are not contained in 14 CFR Part 71 nor are there any TRSA operating rules in 14 CFR Part 91. Part of the Airport Radar Service Area (ARSA) program was to eventually replace all TRSAs. However, the ARSA requirements became relatively stringent and it was subsequently decided that TRSAs would have to meet ARSA criteria before they would be converted. TRSAs do not fit into any of the U.S. airspace classes; therefore, they will continue to be non-Part 71 airspace areas where participating pilots can receive additional radar services which have been redefined as TRSA Service.

- b. **TRSAs.** The primary airport(s) within the TRSA become(s) Class D airspace. The remaining portion of the TRSA overlies other controlled airspace which is normally Class E airspace beginning at 700 or 1,200 feet and established to transition to/from the en route/terminal environment.
- c. **Participation.** Pilots operating under VFR are encouraged to contact the radar approach control and avail themselves of the TRSA Services. However, participation is voluntary on the part of the pilot. See Chapter 4, Air Traffic Control, for details and procedures.
- d. **Charts.** TRSAs are depicted on VFR sectional and terminal area charts with a solid black line and altitudes for each segment. The Class D portion is charted with a blue segmented line.

3-5-7 SPECIAL AIR TRAFFIC RULES (SATR) AND SPECIAL FLIGHT RULES AREA (SFRA)

- a. **Background.** The Code of Federal Regulations (CFR) prescribes special air traffic rules for aircraft operating within the boundaries of certain designated airspace. These areas are listed in 14 CFR Part 93 and can be found throughout the NAS. Procedures, nature of operations, configuration, size, and density of traffic vary among the identified areas.
- b. **SFRAs.** Airspace of defined dimensions, above land areas or territorial waters, within which the flight of aircraft is subject to the rules set forth in 14 CFR Part 93, unless otherwise authorized by air traffic control. Not all areas listed in 14 CFR Part 93 are designated SFRA, but special air traffic rules apply to all areas described in 14 CFR Part 93.

REFERENCE—

14 CFR Part 93, Special Air Traffic Rules

FAA Order JO 7110.65, Para 9-2-10, Special Air Traffic Rules (SATR) and Special Flight Rules Area (SFRA)

PCG — Special Air Traffic Rules (SATR)

- c. **Participation.** Each person operating an aircraft to, from, or within airspace designated as a SATR area or SFRA must adhere to the special air traffic rules set forth in 14 CFR Part 93, as applicable, unless otherwise authorized or required by ATC.
- d. **Charts.** SFRAs are depicted on VFR sectional, terminal area, and helicopter route charts. (See FIG 3-5-4.)

US 3-5
SECTION 5. OTHER AIRSPACE AREASFIGURE 3-5-4
SFRA Boundary

- e. Additional information and resources regarding SFRA, including procedures for flight in individual areas, may be found on the FAA Safety website at www.faasafety.gov.

3-5-8 WEATHER RECONNAISSANCE AREA (WRA)

- General.** Hurricane Hunters from the United States Air Force Reserve 53rd Weather Reconnaissance Squadron (WRS) and the National Oceanic and Atmospheric Administration (NOAA) Aircraft Operations Center (AOC) operate weather reconnaissance/research aircraft missions, in support of the National Hurricane Operations Plan (NHOP), to gather meteorological data on hurricanes and tropical cyclones. 53rd WRS and NOAA AOC aircraft normally conduct these missions in airspace identified in a published WRA Notice to Air Missions (NOTAM).
- WRAs.** Airspace with defined dimensions and published by a NOTAM, which is established to support weather reconnaissance/research flights. ATC services are not provided within WRAs. Only participating weather reconnaissance/research aircraft from the 53rd WRS and NOAA AOC are permitted to operate within a WRA. A WRA may only be established in airspace within U. S. Flight Information Regions (FIR) outside of U. S. territorial airspace.
- A published WRA NOTAM describes the airspace dimensions of the WRA and the expected activities within the WRA. WRAs may border adjacent foreign FIRs, but are wholly contained within U.S. FIRs. As ATC services are not provided within a WRA, non-participating aircraft should avoid WRAs, and IFR aircraft should expect to be rerouted to avoid WRAs.

3-5-9 OTHER NON-CHARTED AIRSPACE AREAS

- Stationary or Moving Altitude Reservation (ALTRV).** A Stationary or Moving ALTRV is announced via an airspace NOTAM issued by the Central Altitude Reservation Facility (CARF) or ARTCC. These announcements will appear in CARF and/or ARTCC NOTAMS.

US 3-5

SECTION 5. OTHER AIRSPACE AREAS

This airspace ensures non-participating IFR aircraft remain separated from special activity. Non-participating VFR aircraft are permitted to fly through the area but should exercise vigilance.

- b. **ATC ASSIGNED AIRSPACE.** Airspace of defined vertical/lateral limits, assigned by ATC, for the purpose of providing air traffic segregation between the specified activities being conducted within the assigned airspace and other IFR air traffic. ATCAA locations and scheduled activation information can be found on the FAA SUA website; a NOTAM will not be issued to announce the activation of this airspace.

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

4-1-1 AIR ROUTE TRAFFIC CONTROL CENTERS

Centers are established primarily to provide air traffic service to aircraft operating on IFR flight plans within controlled airspace, and principally during the en route phase of flight.

4-1-2 CONTROL TOWERS

Towers have been established to provide for a safe, orderly and expeditious flow of traffic on and in the vicinity of an airport. When the responsibility has been so delegated, towers also provide for the separation of IFR aircraft in the terminal areas.

REFERENCE—*AIM, Paragraph 5-4-3, Approach Control.*

4-1-3 FLIGHT SERVICE STATIONS

Flight Service Stations (FSSs) are air traffic facilities that provide pilot briefings, flight plan processing, en route flight advisories, search and rescue services, and assistance to lost aircraft and aircraft in emergency situations. FSSs also relay ATC clearances, process Notices to Air Missions, and broadcast aviation weather and aeronautical information. In Alaska, designated FSSs also take weather observations, and provide Airport Advisory Services (AAS).

4-1-4 RECORDING AND MONITORING

- a. Calls to air traffic control (ATC) facilities (ARTCCs, Towers, FSSs, Central Flow, and Operations Centers) over radio and ATC operational telephone lines (lines used for operational purposes such as controller instructions, briefings, opening and closing flight plans, issuance of IFR clearances and amendments, counter hijacking activities, etc.) may be monitored and recorded for operational uses such as accident investigations, accident prevention, search and rescue purposes, specialist training and evaluation, and technical evaluation and repair of control and communications systems.
- b. Where the public access telephone is recorded, a beeper tone is not required. In place of the "beep" tone the FCC has substituted a mandatory requirement that persons to be recorded be given notice they are to be recorded and give consent. Notice is given by this entry, consent to record is assumed by the individual placing a call to the operational facility.

4-1-5 COMMUNICATIONS RELEASE OF IFR AIRCRAFT LANDING AT AN AIRPORT WITHOUT AN OPERATING CONTROL TOWER

Aircraft operating on an IFR flight plan, landing at an airport without an operating control tower will be advised to change to the airport advisory frequency when direct communications with ATC are no longer required. Towers and centers do not have nontower airport traffic and runway in use information. The instrument approach may not be aligned with the runway in use; therefore, if the information has not already been obtained, pilots should make an expeditious change to the airport advisory frequency when authorized.

REFERENCE—*AIM, Paragraph 5-4-4, Advance Information on Instrument Approach.*

US 4-1
SECTION 1. SERVICES AVAILABLE TO PILOTS
4-1-6 PILOT VISITS TO AIR TRAFFIC FACILITIES

Pilots are encouraged to participate in local pilot/air traffic control outreach activities. However, due to security and workload concerns, requests for air traffic facility visits may not always be approved. Therefore, visit requests should be submitted through the air traffic facility as early as possible. Pilots should contact the facility and advise them of the number of persons in the group, the time and date of the proposed visit, and the primary interest of the group. The air traffic facility will provide further instructions if a request can be approved.

REFERENCE—FAA Order 1600.69, *FAA Facility Security Management Program*.

4-1-7 OPERATION RAIN CHECK

Operation Rain Check is a program designed and managed by local air traffic control facility management. Its purpose is to familiarize pilots and aspiring pilots with the ATC system, its functions, responsibilities and benefits.

REFERENCE—

FAA Order JO 7210.3, Paragraph 4-2-2, Pilot Education.

FAA Order 1600.69, FAA Facility Security Management Program.

**4-1-8 APPROACH CONTROL SERVICE FOR VFR ARRIVING
AIRCRAFT**

- a. Numerous approach control facilities have established programs for arriving VFR aircraft to contact approach control for landing information. This information includes: wind, runway, and altimeter setting at the airport of intended landing. This information may be omitted if contained in the Automatic Terminal Information Service (ATIS) broadcast and the pilot states the appropriate ATIS code.

NOTE: *Pilot use of “have numbers” does not indicate receipt of the ATIS broadcast. In addition, the controller will provide traffic advisories on a workload permitting basis.*

- b. Such information will be furnished upon initial contact with concerned approach control facility. The pilot will be requested to change to the *tower* frequency at a predetermined time or point, to receive further landing information.
- c. Where available, use of this procedure will not hinder the operation of VFR flights by requiring excessive spacing between aircraft or devious routing.
- d. Compliance with this procedure is not mandatory but pilot participation is encouraged.

REFERENCE—AIM, Paragraph 4-1-18, *Terminal Radar Services for VFR Aircraft*.

NOTE: *Approach control services for VFR aircraft are normally dependent on ATC radar. These services are not available during periods of a radar outage.*

**4-1-9 TRAFFIC ADVISORY PRACTICES AT AIRPORTS WITHOUT
OPERATING CONTROL TOWERS**

(See TBL 4-1-1.)

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

a. Airport Operations Without Operating Control Tower

1. There is no substitute for alertness while in the vicinity of an airport. It is essential that pilots be alert and look for other traffic and exchange traffic information when approaching or departing an airport without an operating control tower. This is of particular importance since other aircraft may not have communication capability or, in some cases, pilots may not communicate their presence or intentions when operating into or out of such airports. To achieve the greatest degree of safety, it is essential that:
 - (a) All radio-equipped aircraft transmit/receive on a common frequency identified for the purpose of airport advisories; and
 - (b) Pilots use the correct airport name, as identified in appropriate aeronautical publications, to reduce the risk of confusion when communicating their position, intentions, and/or exchanging traffic information.
2. An airport may have a full or part-time tower or FSS located on the airport, a full or part-time UNICOM station or no aeronautical station at all. There are three ways for pilots to communicate their intention and obtain airport/traffic information when operating at an airport that does not have an operating tower: by communicating with an FSS, a UNICOM operator, or by making a self-announce broadcast.

NOTE: FSS airport advisories are available only in Alaska.

3. Many airports are now providing completely automated weather, radio check capability and airport advisory information on an automated UNICOM system. These systems offer a variety of features, typically selectable by microphone clicks, on the UNICOM frequency. Availability of the automated UNICOM will be published in the Chart Supplement U.S. and approach charts.

b. Communicating on a Common Frequency

1. The key to communicating at an airport without an operating control tower is selection of the correct common frequency. The acronym CTAF which stands for Common Traffic Advisory Frequency, is synonymous with this program. A CTAF is a frequency designated for the purpose of carrying out airport advisory practices while operating to or from an airport without an operating control tower. The CTAF may be a UNICOM, MULTICOM, FSS, or tower frequency and is identified in appropriate aeronautical publications.

NOTE: FSS frequencies are available only in Alaska.

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

TABLE 4-1-1 Summary of Recommended Communication Procedures

	Facility at Airport	Frequency Use	Communication/Broadcast Procedures		
			Outbound	Inbound	Practice Instrument Approach
1.	UNICOM (No Tower or FSS)	Communicate with UNICOM station on published CTAF frequency (122.7; 122.8; 122.725; 122.975; or 123.0). If unable to contact UNICOM station, use self-announce procedures on CTAF.	Before taxiing and before taxiing on the runway for departure.	10 miles out. Entering downwind, base, and final. Leaving the runway.	
2.	No Tower, FSS, or UNICOM	Self-announce on MULTICOM frequency 122.9.	Before taxiing and before taxiing on the runway for departure.	10 miles out. Entering downwind, base, and final. Leaving the runway.	Departing final approach fix (name) or on final approach segment inbound.
3.	No Tower in operation, FSS open (Alaska only)	Communicate with FSS on CTAF frequency.	Before taxiing and before taxiing on the runway for departure.	10 miles out. Entering downwind, base, and final. Leaving the runway.	Approach completed/terminated.
4.	FSS Closed (No Tower)	Self-announce on CTAF.	Before taxiing and before taxiing on the runway for departure.	10 miles out. Entering downwind, base, and final. Leaving the runway.	
5.	Tower or FSS not in operation	Self-announce on CTAF.	Before taxiing and before taxiing on the runway for departure.	10 miles out. Entering downwind, base, and final. Leaving the runway.	

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

TABLE 4-1-1 Summary of Recommended Communication Procedures (continued)

	Facility at Airport	Frequency Use	Communication/Broadcast Procedures		
			Outbound	Inbound	Practice Instrument Approach
6.	Designated CTAF Area (Alaska Only)	Self-announce on CTAF designated on chart or Chart Supplement Alaska.	Before taxiing and before taxiing on the runway for departure until leaving designated area.	When entering designated CTAF area.	

2. **CTAF (Alaska Only).** In Alaska, a CTAF may also be designated for the purpose of carrying out advisory practices while operating in designated areas with a high volume of VFR traffic.
3. The CTAF frequency for a particular airport or area is contained in the Chart Supplement U.S., Chart Supplement Alaska, Alaska Terminal Publication, Instrument Approach Procedure Charts, and Instrument Departure Procedure (DP) Charts. Also, the CTAF frequency can be obtained by contacting any FSS. Use of the appropriate CTAF, combined with a visual alertness and application of the following recommended good operating practices, will enhance safety of flight into and out of all uncontrolled airports.

c. Recommended Traffic Advisory Practices

1. Pilots of inbound traffic should monitor and communicate as appropriate on the designated CTAF from 10 miles to landing. Pilots of departing aircraft should monitor/communicate on the appropriate frequency from start-up, during taxi, and until 10 miles from the airport unless the CFRs or local procedures require otherwise.
2. Pilots of aircraft conducting other than arriving or departing operations at altitudes normally used by arriving and departing aircraft should monitor/communicate on the appropriate frequency while within 10 miles of the airport unless required to do otherwise by the CFRs or local procedures. Such operations include parachute jumping/dropping, en route, practicing maneuvers, etc.
3. In Alaska, pilots of aircraft conducting other than arriving or departing operations in designated CTAF areas should monitor/communicate on the appropriate frequency while within the designated area, unless required to do otherwise by CFRs or local procedures. Such operations include parachute jumping/dropping, en route, practicing maneuvers, etc.

REFERENCE—AIM, Paragraph 3-5-4, Parachute Jump Aircraft Operations.

d. Airport Advisory/Information Services Provided by a FSS

1. There are two advisory type services provided at selected airports.

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

- (a) Local Airport Advisory (LAA) is available only in Alaska and provided at airports that have a FSS physically located on the airport, which does not have a control tower or where the tower is operated on a part-time basis. The CTAF for LAA airports is disseminated in the appropriate aeronautical publications.
 - (b) Remote Airport Information Service (RAIS) is provided in support of special events at nontowered airports by request from the airport authority.
2. In communicating with a CTAF FSS, check the airport's automated weather and establish two-way communications before transmitting outbound/inbound intentions or information. An inbound aircraft should initiate contact approximately 10 miles from the airport, reporting aircraft identification and type, altitude, location relative to the airport, intentions (landing or over flight), possession of the automated weather, and request airport advisory or airport information service. A departing aircraft should initiate contact before taxiing, reporting aircraft identification and type, VFR or IFR, location on the airport, intentions, direction of take-off, possession of the automated weather, and request airport advisory or information service. Also, report intentions before taxiing onto the active runway for departure. If you must change frequencies for other service after initial report to FSS, return to FSS frequency for traffic update.

(a) Inbound

EXAMPLE: Vero Beach radio, Centurion Six Niner Delta Delta is ten miles south, two thousand, landing Vero Beach. I have the automated weather, request airport advisory.

(b) Outbound

EXAMPLE: Vero Beach radio, Centurion Six Niner Delta Delta, ready to taxi to runway 22, VFR, departing to the southwest. I have the automated weather, request airport advisory.

3. Airport advisory service includes wind direction and velocity, favored or designated runway, altimeter setting, known airborne and ground traffic, NOTAMs, airport taxi routes, airport traffic pattern information, and instrument approach procedures. These elements are varied so as to best serve the current traffic situation. Some airport managers have specified that under certain wind or other conditions designated runways be used. Pilots should advise the FSS of the runway they intend to use.

CAUTION: All aircraft in the vicinity of an airport may not be in communication with the FSS.

e. Information Provided by Aeronautical Advisory Stations (UNICOM)

- 1. UNICOM is a nongovernment air/ground radio communication station which may provide airport information at public use airports where there is no tower or FSS.
- 2. On pilot request, UNICOM stations may provide pilots with weather information, wind direction, the recommended runway, or other necessary information. If the UNICOM fre-

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

quency is designated as the CTAF, it will be identified in appropriate aeronautical publications.

f. Unavailability of Information from FSS or UNICOM

Should LAA by an FSS or Aeronautical Advisory Station UNICOM be unavailable, wind and weather information may be obtainable from nearby controlled airports via Automatic Terminal Information Service (ATIS) or Automated Weather Observing System (AWOS) frequency.

g. Self-Announce Position and/or Intentions

1. **General.** Self-announce is a procedure whereby pilots broadcast their position or intended flight activity or ground operation on the designated CTAF. This procedure is used primarily at airports which do not have an FSS on the airport. The self-announce procedure should also be used if a pilot is unable to communicate with the FSS on the designated CTAF. Pilots stating, "*Traffic in the area, please advise*" is not a recognized Self-Announce Position and/or Intention phrase and should not be used under any condition.
2. If an airport has a tower and it is temporarily closed, or operated on a part-time basis and there is no FSS on the airport or the FSS is closed, use the CTAF to self-announce your position or intentions.
3. Where there is no tower, FSS, or UNICOM station on the airport, use MULTICOM frequency 122.9 for self-announce procedures. Such airports will be identified in appropriate aeronautical information publications.
4. **Straight-in Landings.** The FAA discourages VFR straight-in approaches to landings due to the increased risk of a mid-air collision. However, if a pilot chooses to execute a straight-in approach for landing without entering the airport traffic pattern, the pilot should self-announce their position on the designated CTAF approximately 8 to 10 miles from the airport and coordinate their straight-in approach and landing with other airport traffic. Pilots executing a straight-in approach (IFR or VFR) do not have priority over other aircraft in the traffic pattern, and must comply with the provisions of 14 CFR 91.113 (g), Right-of-way rules.
5. **Traffic Pattern Operations.** All traffic within a 10-mile radius of a non-towered airport or a part-time-towered airport when the control tower is not operating, should monitor and communicate on the designated CTAF when entering the traffic pattern. Pilots operating in the traffic pattern or on a straight-in approach must be alert at all times to other aircraft in the pattern, or conducting straight-in approaches, and communicate their position to avoid a possible traffic conflict. In the airport traffic pattern and while on straight-in approaches to a runway, effective communication and a pilot's responsibility to see-and-avoid are essential mitigations to avoid a possible midair collision. In addition, following established traffic pattern procedures eliminates excessive maneuvering at low altitudes, reducing the risk of loss of aircraft control.

REFERENCE— FAA Advisory Circular (AC) 90-66, *Non-Towered Airport Flight Operations*.

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

6. **Practice Approaches.** Pilots conducting practice instrument approaches should be particularly alert for other aircraft that may be departing in the opposite direction. When conducting any practice approach, regardless of its direction relative to other airport operations, pilots should make announcements on the CTAF as follows:

- (a) Departing the final approach fix, inbound (nonprecision approach) or departing the outer marker or fix used in lieu of the outer marker, inbound (precision approach);
- (b) Established on the final approach segment or immediately upon being released by ATC;
- (c) Upon completion or termination of the approach; and
- (d) Upon executing the missed approach procedure.

7. Departing aircraft should always be alert for arrival aircraft coming from the opposite direction.

8. Recommended self-announce broadcasts: It should be noted that aircraft operating to or from another nearby airport may be making self-announce broadcasts on the same UNICOM or MULTICOM frequency. To help identify one airport from another, the airport name should be spoken at the beginning and end of each self-announce transmission. When referring to a specific runway, pilots should use the runway number and not use the phrase "Active Runway."

(a) Inbound

EXAMPLE: Strawn traffic, Apache Two Two Five Zulu, (position), (altitude), (descending) or entering downwind/base/final (as appropriate) runway one seven full stop, touch-and-go, Strawn.

Strawn traffic Apache Two Two Five Zulu clear of runway one seven Strawn.

(b) Outbound

EXAMPLE: Strawn traffic, Queen Air Seven One Five Five Bravo (location on airport) taxiing to runway two six Strawn.

Strawn traffic, Queen Air Seven One Five Five Bravo departing runway two six. Departing the pattern to the (direction), climbing to (altitude) Strawn.

(c) Practice Instrument Approach

EXAMPLE: Strawn traffic, Cessna Two One Four Three Quebec (position from airport) inbound descending through (altitude) practice (name of approach) approach runway three five Strawn.

Strawn traffic, Cessna Two One Four Three Quebec practice (type) approach completed or terminated runway three five Strawn.

h. **UNICOM Communications Procedures**

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

1. In communicating with a UNICOM station, the following practices will help reduce frequency congestion, facilitate a better understanding of pilot intentions, help identify the location of aircraft in the traffic pattern, and enhance safety of flight:
 - (a) Select the correct UNICOM frequency.
 - (b) State the identification of the UNICOM station you are calling in each transmission.
 - (c) Speak slowly and distinctly.
 - (d) Report approximately 10 miles from the airport, reporting altitude, and state your aircraft type, aircraft identification, location relative to the airport, state whether landing or overflight, and request wind information and runway in use.
 - (e) Report on downwind, base, and final approach.
 - (f) Report leaving the runway.
2. Recommended UNICOM phraseologies:
 - (a) Inbound

PHRASEOLOGY:

FREDERICK UNICOM CESSNA EIGHT ZERO ONE TANGO FOXTROT 10 MILES SOUTHEAST DESCENDING THROUGH (altitude) LANDING FREDERICK, REQUEST WIND AND RUNWAY INFORMATION FREDERICK.

FREDERICK TRAFFIC CESSNA EIGHT ZERO ONE TANGO FOXTROT ENTERING DOWNWIND/BASE/FINAL (as appropriate) FOR RUNWAY ONE NINER (full stop/touch-and-go) FREDERICK.

FREDERICK TRAFFIC CESSNA EIGHT ZERO ONE TANGO FOXTROT CLEAR OF RUNWAY ONE NINER FREDERICK.

- (b) Outbound

PHRASEOLOGY:

FREDERICK UNICOM CESSNA EIGHT ZERO ONE TANGO FOXTROT (location on airport) TAXIING TO RUNWAY ONE NINER, REQUEST WIND AND TRAFFIC INFORMATION FREDERICK.

FREDERICK TRAFFIC CESSNA EIGHT ZERO ONE TANGO FOXTROT DEPARTING RUNWAY ONE NINER. "REMAINING IN THE PATTERN" OR "DEPARTING THE PATTERN TO THE (direction) (as appropriate)" FREDERICK.

4-1-10 IFR APPROACHES/GROUND VEHICLE OPERATIONS

- a. **IFR Approaches.** When operating in accordance with an IFR clearance and ATC approves a change to the advisory frequency, make an expeditious change to the CTAF and employ the recommended traffic advisory procedures.
- b. **Ground Vehicle Operation.** Airport ground vehicles equipped with radios should monitor the CTAF frequency when operating on the airport movement area and remain clear of run-

US 4-1
SECTION 1. SERVICES AVAILABLE TO PILOTS

ways/taxiways being used by aircraft. Radio transmissions from ground vehicles should be confined to safety-related matters.

- c. **Radio Control of Airport Lighting Systems.** Whenever possible, the CTAF will be used to control airport lighting systems at airports without operating control towers. This eliminates the need for pilots to change frequencies to turn the lights on and allows a continuous listening watch on a single frequency. The CTAF is published on the instrument approach chart and in other appropriate aeronautical information publications.

4-1-11 DESIGNATED UNICOM/MULTICOM FREQUENCIES

Frequency use

- a. The following listing depicts UNICOM and MULTICOM frequency uses as designated by the Federal Communications Commission (FCC). (See TBL 4-1-2.)

TABLE 4-1-2 Unicom/Multicom Frequency Usage

Use	Frequency
Airports without an operating control tower.	122.700
	122.725
	122.800
	122.975
	123.000
	123.050
	123.075
(MULTICOM FREQUENCY) Activities of a temporary, seasonal, emergency nature or search and rescue, as well as, airports with no tower, FSS, or UNICOM.	122.900
(MULTICOM FREQUENCY) Forestry management and fire suppression, fish and game management and protection, and environmental monitoring and protection.	122.925
Airports with a control tower or FSS on airport.	122.950

NOTE:

- In some areas of the country, frequency interference may be encountered from nearby airports using the same UNICOM frequency. Where there is a problem, UNICOM operators are encouraged to develop a "least interference" frequency assignment plan for airports concerned using the frequencies designated for airports without operating con-*

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

trol towers. UNICOM licensees are encouraged to apply for UNICOM 25 kHz spaced channel frequencies. Due to the extremely limited number of frequencies with 50 kHz channel spacing, 25 kHz channel spacing should be implemented. UNICOM licensees may then request FCC to assign frequencies in accordance with the plan, which FCC will review and consider for approval.

2. Wind direction and runway information may not be available on UNICOM frequency 122.950.

b. The following listing depicts other frequency uses as designated by the Federal Communications Commission (FCC). (See TBL 4-1-3.)

TABLE 4-1-3 Other Frequency Usage Designated by FCC

Use	Frequency
Air-to-air communication (private fixed wing aircraft).	122.750
Helicopter air-to-air communications; air traffic control operations.	123.025
Aviation instruction, Glider, Hot Air Balloon (not to be used for advisory service).	123.300 123.500
Assignment to flight test land and aircraft stations (not for air-to-air communication except for those aircraft operating in an oceanic FIR).	123.400 ¹ 123.450 ²

¹This frequency is available only to itinerant stations that have a requirement to be periodically transferred to various locations.

²Mobile station operations on these frequencies are limited to an area within 320km (200 mi) of an associated flight test land station.

4-1-12 USE OF UNICOM FOR ATC PURPOSES

UNICOM service may be used for ATC purposes, only under the following circumstances:

- Revision to proposed departure time.
- Takeoff, arrival, or flight plan cancellation time.
- ATC clearance, provided arrangements are made between the ATC facility and the UNICOM licensee to handle such messages.

4-1-13 AUTOMATIC TERMINAL INFORMATION SERVICE (ATIS)

- ATIS is the continuous broadcast of recorded noncontrol information in selected high activity terminal areas. Its purpose is to improve controller effectiveness and to relieve frequency congestion by automating the repetitive transmission of essential but routine information.

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

The information is continuously broadcast over a discrete VHF radio frequency or the voice portion of a local NAVAID. Arrival ATIS transmissions on a discrete VHF radio frequency are engineered according to the individual facility requirements, which would normally be a protected service volume of 20 NM to 60 NM from the ATIS site and a maximum altitude of 25,000 feet AGL. In the case of a departure ATIS, the protected service volume cannot exceed 5 NM and 100 feet AGL. At most locations, ATIS signals may be received on the surface of the airport, but local conditions may limit the maximum ATIS reception distance and/or altitude. Pilots are urged to cooperate in the ATIS program as it relieves frequency congestion on approach control, ground control, and local control frequencies. The Chart Supplement U.S. indicates airports for which ATIS is provided. [Jeppesen provides ATIS frequency information on Instrument Approach and Airport Charts, Airport Directory and Jepp-Guide.]

b. ATIS information includes:

1. Airport/facility name
2. Phonetic letter code
3. Time of the latest weather sequence (UTC)
4. Weather information consisting of:
 - (a) Wind direction and velocity
 - (b) Visibility
 - (c) Obstructions to vision
 - (d) Present weather consisting of: sky condition, temperature, dew point, altimeter, a density altitude advisory when appropriate, and other pertinent remarks included in the official weather observation
5. Instrument approach and runway in use.

The ceiling/sky condition, visibility, and obstructions to vision may be omitted from the ATIS broadcast if the ceiling is above 5,000 feet and the visibility is more than 5 miles. The departure runway will only be given if different from the landing runway except at locations having a separate ATIS for departure. The broadcast may include the appropriate frequency and instructions for VFR arrivals to make initial contact with approach control. Pilots of aircraft arriving or departing the terminal area can receive the continuous ATIS broadcast at times when cockpit duties are least pressing and listen to as many repeats as desired. ATIS broadcast must be updated upon the receipt of any official hourly and special weather. A new recording will also be made when there is a change in other pertinent data such as runway change, instrument approach in use, etc.

EXAMPLE: "Dulles International information Sierra. One four zero zero zulu. Wind three five zero at eight. Visibility one zero. Ceiling four thousand five hundred broken. Temperature three four. Dew point two eight. Altimeter three zero one zero. ILS runway one right approach in use. Departing runway three zero. Advise on initial contact you have information sierra."

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

- c. Pilots should listen to ATIS broadcasts whenever ATIS is in operation.
- d. Pilots should notify controllers on initial contact that they have received the ATIS broadcast by repeating the alphabetical code word appended to the broadcast.

EXAMPLE: "Information Sierra received."

- e. When a pilot acknowledges receipt of the ATIS broadcast, controllers may omit those items contained in the broadcast if they are current. Rapidly changing conditions will be issued by ATC and the ATIS will contain words as follows:

EXAMPLE: "Latest ceiling/visibility/altimeter/wind/ (other conditions) will be issued by approach control/tower."

NOTE: *The absence of a sky condition or ceiling and/or visibility on ATIS indicates a sky condition or ceiling of 5,000 feet or above and visibility of 5 miles or more. A remark may be made on the broadcast, "the weather is better than 5000 and 5," or the existing weather may be broadcast.*

- f. Controllers will issue pertinent information to pilots who do not acknowledge receipt of a broadcast or who acknowledge receipt of a broadcast which is not current.
- g. To serve frequency limited aircraft, FSSs are equipped to transmit on the omnirange frequency at most en route VORs used as ATIS voice outlets. Such communication interrupts the ATIS broadcast. Pilots of aircraft equipped to receive on other FSS frequencies are encouraged to do so in order that these override transmissions may be kept to an absolute minimum.
- h. While it is a good operating practice for pilots to make use of the ATIS broadcast where it is available, some pilots use the phrase "have numbers" in communications with the control tower. Use of this phrase means that the pilot has received wind, runway, and altimeter information ONLY and the tower does not have to repeat this information. It does not indicate receipt of the ATIS broadcast and should never be used for this purpose.

4-1-14 AUTOMATIC FLIGHT INFORMATION SERVICE (AFIS) – ALASKA FSSs ONLY

- a. AFIS is the continuous broadcast of recorded non-control information at airports in Alaska where an FSS provides local airport advisory service. Its purpose is to improve FSS specialist efficiency by reducing frequency congestion on the local airport advisory frequency.
 - 1. The AFIS broadcast will automate the repetitive transmission of essential but routine information (for example, weather, favored runway, braking action, airport NOTAMs, etc.). The information is continuously broadcast over a discrete VHF radio frequency (usually the ASOS frequency).
 - 2. Use of AFIS is not mandatory, but pilots who choose to utilize two-way radio communications with the FSS are urged to listen to AFIS, as it relieves frequency congestion on the local airport advisory frequency. AFIS broadcasts are updated upon receipt of any official hourly and special weather, and changes in other pertinent data.

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

3. When a pilot acknowledges receipt of the AFIS broadcast, FSS specialists may omit those items contained in the broadcast if they are current. When rapidly changing conditions exist, the latest ceiling, visibility, altimeter, wind or other conditions may be omitted from the AFIS and will be issued by the FSS specialist on the appropriate radio frequency.

EXAMPLE: “Kotzebue information ALPHA. One six five five zulu. Wind, two one zero at five; visibility two, fog; ceiling one hundred overcast; temperature minus one two, dew point minus one four; altimeter three one zero five. Altimeter in excess of three one zero zero, high pressure altimeter setting procedures are in effect. Favored runway two six. Weather in Kotzebue surface area is below V-F-R minima – an ATC clearance is required. Contact Kotzebue Radio on 123.6 for traffic advisories and advise intentions. Notice to Air Missions, Hotham NDB out of service. Transcribed Weather Broadcast out of service. Advise on initial contact you have ALPHA.”

NOTE: *The absence of a sky condition or ceiling and/or visibility on Alaska FSS AFIS indicates a sky condition or ceiling of 5,000 feet or above and visibility of 5 miles or more. A remark may be made on the broadcast, “the weather is better than 5000 and 5.”*

- b. Pilots should listen to Alaska FSSs AFIS broadcasts whenever Alaska FSSs AFIS is in operation.

NOTE: *Some Alaska FSSs are open part time and/or seasonally.*

- c. Pilots should notify controllers on initial contact that they have received the Alaska FSSs AFIS broadcast by repeating the phonetic alphabetic letter appended to the broadcast.

EXAMPLE: “Information Alpha received.”

- d. While it is a good operating practice for pilots to make use of the Alaska FSS AFIS broadcast where it is available, some pilots use the phrase “have numbers” in communications with the FSS. Use of this phrase means that the pilot has received wind, runway, and altimeter information ONLY and the Alaska FSS does not have to repeat this information. It does not indicate receipt of the AFIS broadcast and should never be used for this purpose.

4-1-15 RADAR TRAFFIC INFORMATION SERVICE

This is a service provided by radar ATC facilities. Pilots receiving this service are advised of any radar target observed on the radar display which may be in such proximity to the position of their aircraft or its intended route of flight that it warrants their attention. This service is not intended to relieve the pilot of the responsibility for continual vigilance to see and avoid other aircraft.

a. Purpose of the Service

1. The issuance of traffic information as observed on a radar display is based on the principle of assisting and advising a pilot that a particular radar target's position and track indicates it may intersect or pass in such proximity to that pilot's intended flight path that it warrants attention. This is to alert the pilot to the traffic, to be on the lookout for it, and thereby be in a better position to take appropriate action should the need arise.

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

2. Pilots are reminded that the surveillance radar used by ATC does not provide altitude information unless the aircraft is equipped with Mode C and the radar facility is capable of displaying altitude information.

b. Provisions of the Service

1. Many factors, such as limitations of the radar, volume of traffic, controller workload and communications frequency congestion, could prevent the controller from providing this service. Controllers possess complete discretion for determining whether they are able to provide or continue to provide this service in a specific case. The controller's reason against providing or continuing to provide the service in a particular case is not subject to question nor need it be communicated to the pilot. In other words, the provision of this service is entirely dependent upon whether controllers believe they are in a position to provide it. Traffic information is routinely provided to all aircraft operating on IFR flight plans except when the pilot declines the service, or the pilot is operating within Class A airspace. Traffic information may be provided to flights not operating on IFR flight plans when requested by pilots of such flights.

NOTE: Radar ATC facilities normally display and monitor both primary and secondary radar as well as ADS-B, except that secondary radar or ADS-B may be used as the sole display source in Class A airspace, and under some circumstances outside of Class A airspace (beyond primary coverage and in en route areas where only secondary and/or ADS-B is available). Secondary radar and/or ADS-B may also be used outside Class A airspace as the sole display source when the primary radar is temporarily unusable or out of service. Pilots in contact with the affected ATC facility are normally advised when a temporary outage occurs; i.e., "primary radar out of service; traffic advisories available on transponder or ADS-B aircraft only." This means simply that only aircraft that have transponders and ADS-B installed and in use will be depicted on ATC displays when the primary and/or secondary radar is temporarily out of service.

2. When receiving VFR radar advisory service, pilots should monitor the assigned frequency at all times. This is to preclude controllers' concern for radio failure or emergency assistance to aircraft under the controller's jurisdiction. VFR radar advisory service does not include vectors away from conflicting traffic unless requested by the pilot. When advisory service is no longer desired, advise the controller before changing frequencies and then change your transponder code to 1200, if applicable. Pilots should also inform the controller when changing VFR cruising altitude. Except in programs where radar service is automatically terminated, the controller will advise the aircraft when radar is terminated.

NOTE: Participation by VFR pilots in formal programs implemented at certain terminal locations constitutes pilot request. This also applies to participating pilots at those locations where arriving VFR flights are encouraged to make their first contact with the tower on the approach control frequency.

- c. **Issuance of Traffic Information.** Traffic information will include the following concerning a target which may constitute traffic for an aircraft that is:

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

1. Radar identified

- (a) Azimuth from the aircraft in terms of the 12 hour clock, or
- (b) When rapidly maneuvering civil test or military aircraft prevent accurate issuance of traffic as in (a) above, specify the direction from an aircraft's position in terms of the eight cardinal compass points (N, NE, E, SE, S, SW, W, NW). This method must be terminated at the pilot's request.
- (c) Distance from the aircraft in nautical miles;
- (d) Direction in which the target is proceeding; and
- (e) Type of aircraft and altitude if known.

EXAMPLE: Traffic 10 o'clock, 3 miles, west-bound (type aircraft and altitude, if known, of the observed traffic). The altitude may be known, by means of Mode C, but not verified with the pilot for accuracy. (To be valid for separation purposes by ATC, the accuracy of Mode C readouts must be verified. This is usually accomplished upon initial entry into the radar system by a comparison of the readout to pilot stated altitude, or the field elevation in the case of continuous readout being received from an aircraft on the airport.) When necessary to issue traffic advisories containing unverified altitude information, the controller will issue the indicated altitude of the aircraft. The pilot may upon receipt of traffic information, request a vector (heading) to avoid such traffic. The vector will be provided to the extent possible as determined by the controller provided the aircraft to be vectored is within the airspace under the jurisdiction of the controller.

2. Not radar identified

- (a) Distance and direction with respect to a fix;
- (b) Direction in which the target is proceeding; and
- (c) Type of aircraft and altitude if known.

EXAMPLE: Traffic 8 miles south of the airport northeast-bound, (type aircraft and altitude if known).

- d. The examples depicted in the following figures point out the possible error in the position of this traffic when it is necessary for a pilot to apply drift correction to maintain this track. This error could also occur in the event a change in course is made at the time radar traffic information is issued.

FIGURE 4-1-1

Induced Error in Position of Traffic

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

EXAMPLE: In FIG 4-1-1 traffic information would be issued to the pilot of aircraft "A" as 12 o'clock. The actual position of the traffic as seen by the pilot of aircraft "A" would be 2 o'clock. Traffic information issued to aircraft "B" would also be given as 12 o'clock, but in this case, the pilot of "B" would see the traffic at 10 o'clock.

FIGURE 4-1-2

Induced Error in Position of Traffic

EXAMPLE: In FIG 4-1-2 traffic information would be issued to the pilot of aircraft "C" as 2 o'clock. The actual position of the traffic as seen by the pilot of aircraft "C" would be 3 o'clock. Traffic information issued to aircraft "D" would be at an 11 o'clock position. Since it is not necessary for the pilot of aircraft "D" to apply wind correction (crab) to remain on track, the actual position of the traffic issued would be correct. Since the radar controller can only observe aircraft track (course) on the radar display, traffic advisories are issued accordingly, and pilots should give due consideration to this fact when looking for reported traffic.

4-1-16 SAFETY ALERT

A safety alert will be issued to pilots of aircraft being controlled by ATC if the controller is aware the aircraft is at an altitude which, in the controller's judgment, places the aircraft in unsafe proximity to terrain, obstructions or other aircraft. The provision of this service is contingent upon the capability of the controller to have an awareness of a situation involving unsafe proximity to terrain, obstructions and uncontrolled aircraft. The issuance of a safety alert cannot be mandated, but it can be expected on a reasonable, though intermittent basis. Once the alert is issued, it is solely the pilot's prerogative to determine what course of action, if any, to take. This procedure is intended for use in time critical situations where aircraft safety is in question. Noncritical situations should be handled via the normal traffic alert procedures.

a. Terrain or Obstruction Alert

1. Controllers will immediately issue an alert to the pilot of an aircraft under their control when they recognize that the aircraft is at an altitude which, in their judgment, may be in an unsafe proximity to terrain/obstructions. The primary method of detecting unsafe proximity is through Mode C automatic altitude reports.

EXAMPLE: Low altitude alert Cessna Three Four Juliet, check your altitude immediately. And if the aircraft is not yet on final approach, the MVA (MEA/MIA/MOCA) in your area is six thousand.

2. Most En Route and Terminal radar facilities have an automated function which, if operating, alerts controllers when a tracked Mode C equipped aircraft under their control is

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

below or is predicted to be below a predetermined minimum safe altitude. This function, called Minimum Safe Altitude Warning (MSAW), is designed solely as a controller aid in detecting potentially unsafe aircraft proximity to terrain/obstructions. The radar facility will, when MSAW is operating, provide MSAW monitoring for all aircraft with an operating Mode C altitude encoding transponder that are tracked by the system and are:

- (a) Operating on an IFR flight plan; or
- (b) Operating VFR and have requested MSAW monitoring.

NOTE: *Pilots operating VFR may request MSAW monitoring if their aircraft are equipped with Mode C transponders.*

EXAMPLE: Apache Three Three Papa request MSAW monitoring.

- 3. Due to the lack of terrain and obstacle clearance data, accurate automation databases may not be available for providing MSAW information to aircraft overflying Mexico and Canada. Air traffic facilities along the United States/Mexico/Canada borders may have MSAW computer processing inhibited where accurate terrain data is not available.

b. Aircraft Conflict Alert.

- 1. Controllers will immediately issue an alert to the pilot of an aircraft under their control if they are aware of another aircraft which is not under their control, at an altitude which, in the controller's judgment, places both aircraft in unsafe proximity to each other. With the alert, when feasible, the controller will offer the pilot the position of the traffic if time permits and an alternate course(s) of action. Any alternate course(s) of action the controller may recommend to the pilot will be predicated only on other traffic being worked by the controller.

EXAMPLE: American Three, traffic alert, (position of traffic, if time permits), advise you turn right/left heading (degrees) and/or climb/descend to (altitude) immediately.

4-1-17 RADAR ASSISTANCE TO VFR AIRCRAFT

- a. Radar equipped FAA ATC facilities provide radar assistance and navigation service (vectors) to VFR aircraft provided the aircraft can communicate with the facility, are within radar coverage, and can be radar identified.
- b. Pilots should clearly understand that authorization to proceed in accordance with such radar navigational assistance does not constitute authorization for the pilot to violate CFRs. In effect, assistance provided is on the basis that navigational guidance information issued is advisory in nature and the job of flying the aircraft safely, remains with the pilot.
- c. In many cases, controllers will be unable to determine if flight into instrument conditions will result from their instructions. To avoid possible hazards resulting from being vectored into IFR conditions, pilots should keep controllers advised of the weather conditions in which they are operating and along the course ahead.
- d. Radar navigation assistance (vectors) may be initiated by the controller when one of the following conditions exist:

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

1. The controller suggests the vector and the pilot concurs.
 2. A special program has been established and vectoring service has been advertised.
 3. In the controller's judgment the vector is necessary for air safety.
- e. Radar navigation assistance (vectors) and other radar derived information may be provided in response to pilot requests. Many factors, such as limitations of radar, volume of traffic, communications frequency, congestion, and controller workload could prevent the controller from providing it. Controllers have complete discretion for determining if they are able to provide the service in a particular case. Their decision not to provide the service in a particular case is not subject to question.

4-1-18 TERMINAL RADAR SERVICES FOR VFR AIRCRAFT

a. Basic Radar Service:

1. In addition to the use of radar for the control of IFR aircraft, all commissioned radar facilities provide the following basic radar services for VFR aircraft:
 - (a) Safety alerts.
 - (b) Traffic advisories.
 - (c) Limited radar vectoring (on a workload permitting basis).
 - (d) Sequencing at locations where procedures have been established for this purpose and/or when covered by a Letter of Agreement.

NOTE: When the stage services were developed, two basic radar services (traffic advisories and limited vectoring) were identified as "Stage I." This definition became unnecessary and the term "Stage I" was eliminated from use. The term "Stage II" has been eliminated in conjunction with the airspace reclassification, and sequencing services to locations with local procedures and/or letters of agreement to provide this service have been included in basic services to VFR aircraft. These basic services will still be provided by all terminal radar facilities whether they include Class B, Class C, Class D or Class E airspace. "Stage III" services have been replaced with "Class B" and "TRSA" service where applicable.

2. Vectoring service may be provided when requested by the pilot or with pilot concurrence when suggested by ATC.
3. Pilots of arriving aircraft should contact approach control on the publicized frequency and give their position, altitude, aircraft call sign, type aircraft, radar beacon code (if transponder equipped), destination, and request traffic information.
4. Approach control will issue wind and runway, except when the pilot states "have numbers" or this information is contained in the ATIS broadcast and the pilot states that the current ATIS information has been received. Traffic information is provided on a workload permitting basis. Approach control will specify the time or place at which the pilot is to contact the tower on local control frequency for further landing information. Radar service is automatically terminated and the aircraft need not be advised of termination

US 4-1

SECTION 1. SERVICES AVAILABLE TO PILOTS

when an arriving VFR aircraft receiving radar services to a tower-controlled airport where basic radar service is provided has landed, or to all other airports, is instructed to change to tower or advisory frequency. (See FAA Order JO 7110.65, Air Traffic Control, Paragraph 5-1-9, Radar Service Termination.)

5. Sequencing for VFR aircraft is available at certain terminal locations (see locations listed in the Chart Supplement U.S.). The purpose of the service is to adjust the flow of arriving VFR and IFR aircraft into the traffic pattern in a safe and orderly manner and to provide radar traffic information to departing VFR aircraft. Pilot participation is urged but is not mandatory. Traffic information is provided on a workload permitting basis. Standard radar separation between VFR or between VFR and IFR aircraft is not provided.

- (a) Pilots of arriving VFR aircraft should initiate radio contact on the publicized frequency with approach control when approximately 25 miles from the airport at which sequencing services are being provided. On initial contact by VFR aircraft, approach control will assume that sequencing service is requested. After radar contact is established, the pilot may use pilot navigation to enter the traffic pattern or, depending on traffic conditions, approach control may provide the pilot with routings or vectors necessary for proper sequencing with other participating VFR and IFR traffic en route to the airport. When a flight is positioned behind a preceding aircraft and the pilot reports having that aircraft in sight, the pilot will be instructed to follow the preceding aircraft. THE ATC INSTRUCTION TO FOLLOW THE PRECEDING AIRCRAFT DOES NOT AUTHORIZE THE PILOT TO COMPLY WITH ANY ATC CLEARANCE OR INSTRUCTION ISSUED TO THE PRECEDING AIRCRAFT. If other "nonparticipating" or "local" aircraft are in the traffic pattern, the tower will issue a landing sequence. If an arriving aircraft does not want radar service, the pilot should state "NEGATIVE RADAR SERVICE" or make a similar comment, on initial contact with approach control.
- (b) Pilots of departing VFR aircraft are encouraged to request radar traffic information by notifying ground control, or where applicable, clearance delivery, on initial contact with their request and proposed direction of flight.

EXAMPLE: Xray ground control, November One Eight Six, Cessna One Seventy Two, ready to taxi, VFR southbound at 2,500, have information bravo and request radar traffic information.

NOTE: *Following takeoff, the tower will advise when to contact departure control.*
